46762. RE: [TS-520_820_530_830] a real puzzler / low drive on lower portions of bands

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-01 03:01:58 UTC
From: Craig Roberts
Topic: 46619 Message: 46762

Hi Dave,

The load control is in its normal position(s). The most dramatic demonstration of the anomaly is on 40 meters. At about 7.100 MHz, for instance, in Tune/Send position, rotating the Drive control from full CCW results in no ALC indication until about 12 o'clock when the meter suddenly jumps up to normal readings. In other words, there is no gradual increase in ALC readings. As I mentioned, I have very little drive on the first 50 - 100 KHz of each band on 160, 80 and 40. Everything's normal on the upper bands.

Many thanks and 73,

Craig
W3CRR

fpath fpath <fpath@hotmail.com> wrote:
Craig, Is the load control in or about the normal position or are you finding it hard CCW or CW? 73's Dave VK5PDL To: TS-520_820_530_830@yahoogroups.com From: crgrbrts@verizon.net Date: Tue, 31 Dec 2013 06:10:51 +0000 Subject: [TS-520_820_530_830] a real puzzler / low drive on lower portions of bands Well, we're almost there. ...same TS-830S with the reception problem (now solved with Molex connector pin repair on the AF board). We now have low drive - or no drive -- on the lower portions of the lower bands, i.e., 160, 80 and 40. In other words, using 80 as an example, drive and output are normal at 3.975 MHz but negligible at 3.525 unless I crank the carrier control wide open. Even then, the maximum output is no more than 50 watts. The situation is the same on 160 and 40 meters; everything's fine at the upper ends of the bands but unwell at the lower ends. This anomaly became apparent after the RF board was pulled and replaced for the sake of replacing a 10 meter RF coil. The drive control seems to be at fault here, but I can find no misalignment of capacitor plates or other obvious unpleasantness. Whaddya think? Thanks, Craig W3CRR

Dale,

Which capacitors are your talking about..the HV caps? If so, usually less than 10 minutes...but
NEVER...I say again... NEVER mess around with these...use your volt meter to check to make sure! Kind of a drag to spend the first days of the new year either in the hospital or worse... SK

I know what the screen grid switch does. I burnished the contacts on both relays. In receive, gain is at one level. Toggling transmit and back to receive, receive gain drops down. Switching the rig off and back on recovers gain to where it was. What band is in use doesn't matter.

Jim L.

Suggest you buy an NOS replacement Aux relay from Kens Electronics or Ken K4EAA or Jim HybridRestore while still available. Cleaning usually isnt too long lived especially if have burnished the contacts.

You have two key dc voltages required by the gain controlled RF and IF dual gate mosfets.....AGC and RB (via RLR). These are both switched in RX/TX by the Aux relay contacts. RB is approx -3vdc in TX and +2.0vdc in RX.

Wont take very much drop across relay contacts to affect the gain of RF and IF amps. Would need analog voltmeter to monitor Gate 1 and Gate 2 voltages at transition. Not sure could see it. Would have to look at RB and AGC.

Try swapping the TR and Aux relays as first step. Then monitor RB on RF board.

Have you looked at VC-1, VC-2, VC-3 drive chains to make sure aligned correctly and no dead band. Especially important for Mixer and Drive to be in sync and no lead or lag. Drive control and ALC peak will be touchy if they are not in sync.

At 1200 all three cap plates should be close to 50% meshed.

On 40 meters at 300 should see ALC peak around 2:00 oclock on Drive control and at 50 should see ALC peak around 10:00 oclock.

Watch the plates of VC-2 and VC-3 and make sure when you rotate the Drive control that they start to move together at same time and same % mesh. VC-1 should do likewise but for TX just focus on the middle and back caps.

Hello All
First a Happy New Year to you all, and may the Hybrids long live!

with the risk being a pain, I wonder if anybody have seen this happen, have put correct x-tal back in an TS 520SE (28,0 - 28,5 part) but now it drop output over 28,2 Mhz.
Have put new slug in 28mhz coil, since the old one was cracked, receive works great, but transmit just drops.....have new good tubes, incl driver....

Maybe I should add that somebody had tried a cb conversion on this rig...

Have I missed something simple or, whats up??

Hope to get this rig out of here, so my friend KA3USM can have the rig back.

Thanks
Lars

Oh yeah, you know how I said high value resistors subjected to high voltage for a long time tend to drift up in value? Guess what happens to bleeder resistors across HT supplies?

Check it, check it again, discharge it with your great big bleeder resistor on croc clips, then check it again. Then go and have a cup of tea, just to make sure it's had enough time.

Use a clip lead with a 100K 1W resistor to ground, firmly touched the hot end of each
 capacitor for several seconds to bleed it off before you touch anything !

I was using my volt meter when it arced between the probe and a couple of pins on the power supply board.
This was at least an hour after being unplugged.
The two main power supply capacitors were discharge.
Thanks (KD0GES)

Hey Terry,

A cursory examination of the variable cap linkage looked okay. (That was the first thing I checked, actually). But, I'll take a much closer look.

This anomaly is most dramatically demonstrated on 40 meters. Drive is very low on the first 75 KHz or so of the band (7.000 - 7.075), but is up to normal levels by about 7.100. However, the drive control acts uncharacteristically. Drive does not gradually increase with clockwise rotation of the drive control, as usual, but resonance appears quite suddenly with a very faint "pop". In other words, I have no ALC indication at, say, 9:59 but full ALC at 10:00 o'clock. Bands above 40 react normally with gradual drive "ramp up".

What's disturbing is that the symptoms appeared after I had removed, repaired and replaced the RF board. So, it is somehow my re-install that's at fault here. Something is badly out of kilter.
*
Say, what's the purpose of the blue wire soldered to the underside of VC-3? My radio, schematic and I are in separate venues at the moment. *

Oh -- you may be happy to know that my latest acquisition in my quest to rebuild a decent service bench -- and regain skills - is a Hakko 808 desoldering kit. It arrived yesterday but I have not yet had the opportunity to put it through its paces. Looks pretty nice.

VY 73,

Craig

Craig:

The Blue wire is your RF drive.

You will love the Hakko 808 and wonder how you ever got along without one. Makes childs play out of unsoldering the vertical bandswitch wafers pins on the RF board. Every so often will find one of the pins has been folded over and soldered and will take a little work, but generally components will just fall out of the board using the 808 gun.

First time I did a 14 pin IC I got a chuckle.

Did you do any work on 7mhz Mixer and Drive coils? Any soldering?

Did coil pack alignment go well with Drive control at 1200 and following the proper band sequence and VFO setting? Did 160 and 80 go well and then encounter problem with 40? I would think you would have seen problem trying to do the coil pack alignment or is that what you are describing?

Tell us again what coil you replaced. I think it was L21 Mixer? Was that only work you did on the board? Did you test the replacement coil prior to install in any way? Like measure resistance and inductance and compare to the one removed? I assume the removed one was not open or shorted winding just stuck core?

Discharging the HV caps will not prevent arcs and shocks on the Rect and Final boards as the 300 and 210 caps will remain charged for a long time. I and others have cautioned about this several times on this forum in past.

Why no-none here has even mentioned having, making, or using what we called a "Zap Stick" when I was young and stupid, is rather beyond me.

Piece of dowel rod, 10K-100K 1-W resistor stuck (parallel to the long dimension) on the end. Piece of electrical tape works, or a couple of wraps of wire (that only touch the body of the resistor, by the way), some glue, anything to stick it on there. Bend one lead of the resistor to make a hook.

Don't make the resistor lead too short, you're going to be needing to reach into some tight places and the extra length can help.

Slip a hunk of heat-shrink or stripped-off insulation on the resistor lead before you form the hook, if there is a chance you could short things in a really tight chassis. Leave just the bent end uncovered.

Solder a hunk of insulated 16-ga or so on the other end of the resistor. Some heat-shrink, or tape, or a piece of stripped-out insulation slid over the resistor lead and solder joint. Alligator clip on the other end of the wire.

If you're really paranoid, some wraps of tape on the end of the dowel opposite the resistor.

Clip to the chassis, hook over the capacitor lead. Zap. Wait for a five count or so, no more charge.

If you like sparks (NOT RECOMMENDED), leave off the resistor.

I keep one of these on the bench, and have since I started mucking around with electronics, starting with stripping old tube TVs and radios for parts. One good zap from a capacitor in a TV flyback circuit, that has been sitting a year or more, and you learn to handle them with a little respect.

I agree with Mr. Davidson to use a jumper lead with current limiting resistor instead of a screw driver. I dont do any welding in my rigs or customers rigs.

I dont use a 100K resistor. With a 100k if you dont leave it connected long enough can still have voltage after initial contact. This can even happen if you did get it discharged to 0 volts momentarily. Some refer to this effect as Trapped Charge or Dielectric Compression. I use a 10k resistor. 100K at 900vdc would be approx 10ma so could take some time to fully bleed off. 10k would be closer to 100ma.at full voltage. Just want enough current limiting resistance so arent stressing the caps by dumping lots of energy in a short time. Just dont touch grounding jumper on the caps, but attach it and leave it there for awhile. If you have made a "chicken stick" then you must hold it there for awhile and not just tap it. Better to apply at the filter cap plus leads than at top of Plate choke.

I am also anal and recommend you check your grounding jumper lead by reading it with your ohm meter to ring it before each use so it does not fool you. Could have an open at alligator clips connections at either end.

After discharging your filter caps the absolute best practice is to take a contact voltage reading with a known good voltmeter before you barehand touch. This is called a live-dead-live test. You check the meter and its leads on known energized source, check for presence of voltage on B+ lead where you placed your ground jumper, and then re-check the meter again on energized source. Now you know it is safe to barehand touch.

No electrician or transmitter tech ever got killed following this grounding and voltage testing procedure. Those who did are ones who touched what they thought or believed to be de-energized and dead.

I believe Joe mentioned taking the contact voltage test and he is spot on. Take it like you expect to find something.

What I have told you is best practice. How much of it you observe is up to you.

Wes:

I forgot about the Flybacks with integral capacitors. Even at nano farad values would hold a charge a long time same as the old CRT would act as a capacitor.

The idea of a "chicken stick" with a hook on one end allows you to hang it on B+ and to do so without placing yourself within reaching and falling distance of the high voltage.

I think more commonly employed in high voltage high wattage transmitters.with thousands if not 10s of thousands of anode voltage.

I made my jumper grounding cable using flexible belden 5kv test prod wire and good mueller alligator clips with rubber boots over them. I heat shrinked the series resistor. I clip the ground end alligator to chassis ground screw on rear panel of rig and then I clip the other alligator clip to screw driver and then I hold it on the Plus leads of the filter caps. After a count of 5 or so I unclip from the screw driver and then connect the alligator to the caps plus lead and leave it there until ready to work and then remove and check with voltmeter before I bare hand.

Nothing wrong with the chicken stick tool with a metal hook contact, but I prefer the more positive mechanical and electrical connection of the mueller alligator clip than just a hook making contact.

If I worked on Linear amps with several thousand anode voltage a "chicken stick" or whatever you call it would be a mandatory tool.

By the way I dont recommend grounding at top of the RF plate choke as you have to dump the capacitor energy thru both of the KW hybrid plate choke windings that are in series and no need to stress them. I recommend grounding at the HV filter caps positive terminals. Some people discharge the entire series stack and then do each one individually. In commercial transmitters may be shorting straps that can be connected across each cap.

As I mentioned in first response not good idea to just tap or touch grounding tool on for a moment as voltage on the caps can "regenerate" after removing the ground.

Craig,

Sorry for the delay, but work gets in the way of hobby. Terry has given sound advice as usual. Was going to suggest that the little white gears on VC 1-3 do crack and may have come out of alignment with each other. Make sure that VC1 -3 are all in sync, meaning that when they are fully meshed they are all seated the same. As Terry indicated the blue wire is RF drive, when you removed this wire did you remove all the old solder and start with fresh, but saying this, if there was a high resistance then you'd be seeing similar issues in the higher bands. Seeing this has occurred after you removed the board for repairs, have a look at all the molex foil side of baord for minor crack or have you a solder whisker somewhere? Did you perform full alignment after replacing the coil?

Subject: RE: [TS-520_820_530_830] a real puzzler / low drive on lower portions of bands

Hi Dave,

The load control is in its normal position(s). The most dramatic demonstration of the anomaly is on 40 meters. At about 7.100 MHz, for instance, in Tune/Send position, rotating the Drive control from full CCW results in no ALC indication until about 12 o'clock when the meter suddenly jumps up to normal readings. In other words, there is no gradual increase in ALC readings. As I mentioned, I have very little drive on the first 50 - 100 KHz of each band on 160, 80 and 40. Everything's normal on the upper bands.
Many thanks and 73,
Craig
W3CRR

fpath fpath <fpath@...> wrote:
Craig, Is the load control in or about the normal position or are you finding it hard CCW or CW? 73's Dave VK5PDL To: TS-520_820_530_830@yahoogroups.com From: crgrbrts@verizon.net Date: Tue, 31 Dec 2013 06:10:51 +0000 Subject: [TS-520_820_530_830] a real puzzler / low drive on lower portions of bands Well, we're almost there. ...same TS-830S with the reception problem (now solved with Molex connector pin repair on the AF board). We now have low drive - or no drive -- on the lower portions of the lower bands, i.e., 160, 80 and 40. In other words, using 80 as an example, drive and output are normal at 3.975 MHz but negligible at 3.525 unless I crank the carrier control wide open. Even then, the maximum output is no more than 50 watts. The situation is the same on 160 and 40 meters;

everything's fine at the upper ends of the bands but unwell at the lower ends. This anomaly became apparent after the RF board was pulled and replaced for the sake of replacing a 10 meter RF coil. The drive control seems to be at fault here, but I can find no misalignment of capacitor plates or other obvious unpleasantness. Whaddya think? Thanks, Craig W3CRR

Yup, the Hakko 808 looks kinda like one of those old Weller soldering guns with a conical tip. I can't wait to disassemble something now!

I will be re-aligning my TS-830S shortly. However, given my unpleasant experience with tweaking a coil on the RF board -- the, simple, five minute task that began my latest repair adventure* -- I am awaiting delivery of my can of CorrosionX for Electronics to employ as a coil slug lubricant. I will announce the results.

Many thaks and 73,

Craig
W3CRR

*While adjusting L21 to restore 10 meter drive, I got overly zealous and jammed the slug into the bottom of the coil, then broke off a chunk of it in an attempt to back out the slug. My equally clever subsequent move -- gluing a plastic stick to the top of the damaged slug -- resulted in my accidentally but effectively super-gluing the slug into the coil (archeologists will find this artifact 1,00 years from now). An especially kindly and generous list member donated a replacement L21 to me. My latest round of odd symptoms appeared after I replaced the coil.

CorrosionX? Ok, why not. But with a toothpick to apply it, that is one of the few things for which I actually use WD-40. I don't like it for most anything else...

I've had pretty good luck using it for keeping coil slugs loose, and I've also used "Liquid Wrench" if the slug was stuck. Toothpick application of tiny droplets at the top of the slug, and let it sort of ooze its way down into the slug threads. Usually frees things right up after an hour or two. I've never needed to use the soldering-iron trick, but I'm keeping it in reserve for the next time I run into this.

Ron:

Are you saying you didnt take picture or make drawing and now need to know how to orient each switch wafer to insert the band switch shaft? Not scolding just lesson learned for future.

If so, do this:

1. Place rig on its top. Remove the metal cover plate from S5 band switch.

2. Rotate bandswitch knob so white line is pointing at 29.1 and should see one of the two shaft flats on top facing up. Looking at rear of S5 should see 4 contacts on bottom of the rotation that the shaft wiper tab is making contact with. Look at the thru bolts and start counting from the right side clockwise. Contacts at 4, 5, 6 and 7 oclock positions (approx) should be touching the wiper tab. The wiper tab is quite wide. In other words the wiper tab should range from approx 2 oclock to 7 oclock position. At 8 oclock is the common wiper contact that is engaged at all times.

3. Now uncouple phenolc coupler and pull the shaft rod.

4. Beginning with the Drive Coil board (closest to rear of rig) rotate the wiper so that the wiper tab is at 1030, 1130, 1230 rivet positions.

5. Rotate the wiper tab of the next board (Ant Coil) to same.rivet positions as Step 4.

6. Rotate wiper tab of the next board (Mixer Coil) to same rivet positions as Step 4.

7. The Het Osc board (with the xtals mounted on it) has different style wiper. It has two small wiper tabs. Looking from front of rig they will be at 5 and 6 oclock positions.

8. Reinsert the shaft so flat is up and knob white line is indicating at 29.1mhz. Re-couple the phenolic coupler.

I disavow any responsibilty for glowing final tubes that may result from these instructions! Lets hope not!

Terry K9TW

46792. TS-520SE - Low Audio Receive, VERY high noise floor, worse on the upper end of the band

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-02 01:43:59 UTC
From: Wes Will
Topic: 46619 Message: 46792

I'm about to start another topic, regarding my 520SE.... Hope someone has a good idea to get me going.

I suspect it mostly just needs to be realigned, but I have seen the level of advice going through here for some months now, and suspect it would be about a size-12 case of the STUPIDS if I didn't ask before popping the case on the old girl and diving in with tuner wands and a signal generator.

First, across the board, and even with the dummy-load on, it's NOISY. Even with the antenna shorted to ground, it's NOISY. Very.

Also, receive sensitivity is degraded the higher up the band you go, all bands. The marker signal is the same all the way up, but received signals are very much attenuated at the high end. Using my signal generator feeding a loop of wire and inductively coupling it to the antenna inputs, I see that the same input value from the generator through the coils which produces an S-meter reading of S-9 at the bottom of any of the bands will give only an S-2 or S-3 reading at the top. I do the checking in CW mode, by the way.

I get the same readings using a 0.1 microfarad disc capacitor to couple the RF directly to the antenna input line. I of course lower the output amplitude of the signal generator before doing this. (I'm shooting for injecting a 0dB amplitude signal, fyi, and doing the jiggering and figuring to determine that is bringing back old knowledge from about forever ago.)

For instance:
With the generator tuned to 3.550 MHz, I get an S-9 and a clear, loud signal on the radio. (I use the internal modulation of the old Eico generator, by the way. I have it set to just about 440 Hz.) Tuned to 3.950, I get S-2. Of course I tune BOTH the generator and the receiver, and I check the voltage of the generator with an oscilloscope, the magnitudeof the generator output is the same for both readings, within less than a couple of percent, best I can manage to read it. Same basic variation when the signal is at 14.125 and then 14.450 MHz.

Same readings on CW/USB/LSB, seems to be agnostic about the mode. I use the CW mode for the testing, for the simplicity of measuring the frequencies in the receiver.

So, where do I look first, guys? I could start out just measuring all the levels on the receiver section of the service manual and hoping there was something drastically wrong, but I'm not only not lazy, but

I'm not stupid either. Scatter-gunning repair work is inefficient. I'm too lazy for that, my first degree is in Industrial Engineering which is "how to do anything with the least effort possible," if you're unfamiliar with the field. Null-therbligs, too right. (And the keep telling me it's "Cheaper by the dozen.")

I've got a list of several points that are common to all bands, since it's across the board, and I've got a feeling the very high noise problem is somehow related. Before I go solo on the problem, which I most assuredly will if I don't get better advice from the board, some advice and technique would be appreciated.

Obliged, TIA, mates. Have a good holiday, and cheers.
Na Vashem Zdorove, Tovarishchy.

I buggered up a couple wafer switch contact fingers when I started wire brushing them 3 months ago.
Luckily it was the wafer towards the back edge of the RF board so I was able to do micro surgery with 22 or 24 gauge (I didn't check with gauge and GF dsoesn't remember what is in her jewelry stock) sterling silver wire and silver solder, tiny tip soldering iron.....I did have to pull the board though.
I use a 3 axis Panavise to hold the board in whatever position that works best, holding it immoble while I have both hands free. vaccum or suction base locks it down on the table if I want more stability.
Using 2.5 magnifying reading glasses for my old eyes and a magnifying lamp like you see on K4EAA's bench. "Electronic Microsurgery".

In my zeal and enthusiasm....and being wore out because it took forever....
...I lost track of the position of the wafer rotating disc....it took hours to study the schematic to understand the wafers well enough to get them in sync. There is one tab that sticks up on all wafers, they are all very similar, or identical, I forgot, but you get the idea.

Now, any time I pull an RF board I "match mark" the shafts at the couplings. Using a sharpie, place marks on the shafts, across the coupling and onto the other shaft.
When putting back together just line up the marks. Even a dummie like me won't bugger that method up.
If doing wafer work, replacing or repairing one, study the position of the discs and draw yourself some pictorial notes.
Think through the steps of tightening of the coupling in your head and rehearse it BEFORE removing the old one.
The matchmarks and some hand drawn pictures will save you hours of agravation later. Ask me how I know....
I can swap out a coupling (on some) in about 15 minutes.
Was it the 820S I had to take the front off to pull the shaft?
What a pain.
Buggered one up and it took me 6 hours to sort one out.....
WON'T make that mistake again.

Here's a omplete one in good condition that might go fairly cheap on eBay:
http://www.ebay.com/itm/Kenwood-TS-520S-/221345355134?pt=2_Way_Radios_FRS&hash=item338936157e
Or this one
http://www.ebay.com/itm/Kenwood-TS-520-with-optional-CW-FILTER-Parts-or-Repair-/201011382258?pt=US_Ham_Radio_Transceivers&hash=item2ecd3647f2
Not sure what these boards are, $25 for 2 boards, maybe you could contact this seller if they look like what you need, ask him for board numbers:
http://www.ebay.com/itm/Kenwood-TS-520-Miscellaneous-Parts-Free-Shipping-Con-US-/161103253328?pt=LH_DefaultDomain_0&hash=item2582808f50
You might contact this fellow, his name is Ricardo.
http://www.ebay.com/usr/charro815
I know he has several radios dimantled for selling the components. Right now he's not listing a whole lot, but I know he has quite a stockpile.
At least 4 or 5 radios cut up, parts not listed presently.
I know because i've been buying alot from him
and often check his "store".
Good luck.

Hello again group. Tom in Reno here, W7OA. I sent this post several days ago but I haven't seen it show up yet so maybe it didn't go through for some reason. If it shows up again later, my apologies.
I picked up a TS-520S from ebay - sold as DOA for parts so no ebay story here. Anyway transmit was fine, receive was dead. Traced the problem to the 3rd. IF on the IF board. Q4 was bad - replaced it. Still dead. Came to find T6 IF transformer is open on the secondary. Does anyone have a parts IF board that they would possibly be willing to remove T6 from, or a whole board if the price isn't too steep?

Regards
Tom

I've been bitten by audio amps that way. It's a good learning experience.

What really taught me to check the bleeder resistors aren't open was when I went to short across the beer can sized capacitors in a guitar amp I was building as a teenager, to stop them creeping up - they'd been left for five minutes, they'd surely have discharged through the bleeder, right? - and clapped a screwdriver across the terminals.

Oh well, I needed a short 3mm screwdriver and the tip of that one was pretty chewed *anyway*...

Ron

Your question was framed how to align the hanging board wafer switches to the bandswitch shaft. Could have saved some keystrokes if you had said you had the hanging boards all aligned and just needed to know how to couple its shaft to the S5 switch shaft.

You like to make me work!

Wes:

Couple of points:

1. Is this a new condition?

2. It is normal for Rx gain to be less on 15 and more so on 10 meters. If you look at coil pack will see no small value fixed capacitor across the band switched Ant coil. This is because of the fixed parasitic capacitance that the PC traces and RF amp mosfet present. It forces the KW designers to use a less than optimum LC ratio ie too high an inductor value to resonate the tank circuit. This results in higher loss on 10 meters ie less gain.

So on a well aligned spec TS520SE using the Marker as a test signal source will result in higher S-meter indication on the low bands than on 15 and 10 meters. Should see close to S9 on low bands and falling off to maybe S5 or so on 10 meters. This is a rough test.

3. I assume you are using Eico (324?) and if so you will not be able to use it to accurately measure MDS for several reasons.
A. Cant use your O-scope to measure low signal levels required. 0db (KW Japanese units) is 0.50uv and you cant measure that with your O-scope.

B. You could set Sig gen for 100mv or 283mv P-P (a value you can measure) and attenuate down using an external step attenuator. Would need -106dB attenuation to get down to an accurate 0.50uv or 0dB level and average ham doesnt have that kind of step attenuator. I use a HP 355C and D which works in 1db steps to -132.

C. Even if you had the means to get to accurate 0dB you would not know what your receiver was seeing as these old LC type RF Sig Gens are pretty good transmitters. No idea how much signal is being seen via the test lead connection to the SO-239 and how much is being received via Sig gen leakage. Test is to remove the Sig gen test lead and if you can still hear the signal in the receiver then you know you were kidding yourself. Been there and done that!

4. These old Heath and Eico rf sig gens are good for troubleshooting a dead receiver, but not very useful for calibration and alignment work. No accurate step attenuator and very leaky.

5. As you know receiver noise is the hiss you hear out of the speaker when you have the rig on a dummy load. This normally low level hiss is primarily produced by the Mixers. You have three mixers...Het, VFO, and Product detector. If this noise level you are experiencing is a recent thing then may have a problem with Mixer stage?

6. One way average ham can evaluate his TS520SE is if you have a analog VTVM with dB scales. Here is procedure:
A. Tune to a clear place on the band on 10 meters
B. Switch off antenna to the dummy load

C. Connect your VTVM across the speaker or across a 8 ohm dummy load connected to the remote speaker jack.
D. Set AF gain pot for -10dB on the meter
E. Switch back to your antenna and note the dB reading. Should see something like 3 or 4dB. If you have a beam try swinging it thru 360 degrees and note highest dB.

The service manual around page 43 has the RX Level Diagrams in it. This is the best way to base line your KW hybrid receiver gain . Remember that all the dB figures are Japanese units and not the more familiar American uv or dBm units so you will have to convert. If you dont know how I can help. Need a calculator with anti-log or use log and 2nd key. Very easy. If I can do it anyone can.

The db figures listed are the levels you would inject from a good RF sig gen to produce a constant 0.63V rms output across an 8 ohm dummy load (50 milliwatts of audio output from the speaker). Remember do not want any AGC action when running this test.

Absent a calibrated RF Sig Gen and AF VTVM not possible to run RX level diagrams.

I had seen lots of conversations about soldering kits, and I figured I'd chime in about a deal I found on slickdeals.net showing Radio Shack has a really good 70W digital soldering kit for just under $30 on clearance:

http://slickdeals.net/f/6588268-clearance-radioshack-pro-line-70w-digital-soldering-station-model-gx-881-29-97?

Here's the actual link to the Radio Shack site, but in store they have 25% off on Clearance items, so go in to buy it for the discount - you can't get it online for the discounted price:

http://www.radioshack.com/product/index.jsp?productId=15725446&retainProdsInSession=1

I bought one last week and intend to try it out this weekend.

Slickdeals.net is one of the most helpful sites I've ever seen to save money on just about any kind of item, plus they let you post deal alerts to let you know when something you want is posted. They rarely have ham radio equipment posts (except for the occasional Baofeng posts), but they do have a lot of different types of electronics posted often.

Hope this helps someone!

Topic: 46801 Message: 46801

Hello group,

I wanted to ask what would be the main reason for an unstable vfo when left idling. I put the funcion on my 820 to 25khz and let it sit for a while. Few months before the vfo usually got rock stable after a while and allowed me to work digital modes with ease. Now no matter for how long the vfo is drifting back and forwards like this http://bit.ly/1hXcroc .
It may not seem much, but for digital mode operation thats too much.

What could cause such instability?

Wes:

I realize we all have limits on our discretionary funds. Since I dont smoke or drink I like to think I have a minimum of $400 dollars a month for toys! At least that is how I justify it.

Thinking about a good RF sig gen here are some options:

1. Can find from time to time a HP-606 or a URM-25. Both have good calibrated output, but are loaded with tubes and big and heavy and getting long in the tooth.

2. Wavetek 3002 or SG1170/U (military version). This is a great PLL sig gen. Stable with accurate output attenuator. Dennis K8IFF is the guru near Detroit and he does a fantastic job re-furbing and aligning. Typically run around $200 to $250.

3. Could build a DDS based one. Best to add a good LP filter at output and still need good step attenuator.

4. Elecraft XG-3 is a pocket sized DDS based unit and all you need. It has four commonly used output levels. It can be programmed with your lap top to include the common KW hybrid frequencies and goes built for around $180.00. I have one that I take to hamfests for testing of potential purchases.

5. Elecraft XG-2 is a kit that puts out a calibrated 1uv (-107dBm) and 50uv (-73dBm) signal on 80, 40 and 20 meters on three crystal frequencies. These two output levels are what you need for RF/IF alignment and caling the S-meter. The 1uv level would be ideal for measuring MDS as you would like to do with your 520SE. Does not come in an enclosure. Approx $80.00

6. MFJ-259B. Some folks have this antenna analyzer and have no idea that they have a signal generator with an accurate and stable 2v P-P alc'd output, a frequency counter, and 1.8 to 170 mhz output. All you need to do is add a step attenuator. I dont know about any of the other antenna analyzers as sig gens.

7. Step attenuators include the MFJ unit that is 81 dB in 1 dB steps, Elecraft and Hendricks QRP make 41 dB attenuators. Can buy two and place in series or buy the MFJ and add a homebrew 30 dB T-pad in series. Can make step attenuators but by the time you buy good switches, precision resistors, doublesided PC board for shielding, enclosures, and BNC connectors you will approach cost of commercial unit (depends on how well stocked junk box you have).

So this is some ideas of what you can do regards a RF sig gen that will serve well for KW hybrid work.

If you can borrow a calibrated RF sig gen I can share with you simple procedure to measure MDS. Just need a DMM or VTVM and calculator with Log key. Your TS520SE should be close to -125dBm.

Sample calc:

1. 3.9v rms across speaker with 1 uv (-107dBm) injected into SO-239
2. 0.50v rms across speaker with rig on dummy load
3. 3.9/.5 = 7.8
4. Log of 7.8 = .892
5. .892 x 20 = 17.84
6 -107dBm - 17.84dBm = -124.84dBm

MDS = -125 dBm

> 1. Is this a new condition?

Nope. Working like this since I got the rectifier board back together, actually. Didn't mess with it until I had at least SOME antenna on there, so I've left it alone and pretty much been working on other things. I thought it was off before, but didn't want to bring it up before I had something a little more like reasoning to work with.

> 2. It is normal for Rx gain to be less on 15 and more so on 10 meters.

I know about the interelectrode capacitance issues, and using them to get resonance on 10 meters. I understand the trade-offs with the low-Q coils that were chosen to get at least SOME output on 10, and I've read your posts on the subject as well.

This is not between bands. It is internally consistent on all of the bands, with the higher frequencies showing the same sort of drop-off, just starting from a lower signal strength point on the 'good' (low) end of the band or band segment (in the case of 10).

This is between the top of and the bottom of the same band or band segment; the signal strength drops WAY off. many S units, as you tune UP the band/segment.

> to maybe S5 or so on 10 meters. This is a rough test.

The ten-meter sections marker shows S-7 on the low end of each of the 10M band segments, which drops down to about S-3, barely above the noise floor, on the upper end of any segment.

> 3. I assume you are using Eico (324?) and if so you will not be able to
> use it to accurately measure MDS for several reasons.

Didn't expect it to be good enough, knew it AAMOF, but at the moment it's better than nothing. Barely, but it does give me at least SOME signal to work with.

It's a clean signal buried in a LOT of noise.

> A. Cant use your O-scope to measure low signal levels required. 0db (KW
> Japanese units) is 0.50uv and you cant measure that with your O-scope.

Another, "knew it" but preferred to be told for sure. Wishful thinking. GOTTA upgrade my bench, a lot.

> I use a HP 355C and D which works in 1db steps to -132.

Don't know that I can afford one, but I'd really like a 355C. The D would be nice, but the C would be a god-send. Extremely nice attenuator, and it's all MANUAL, not digitally-anythinged... Much more my speed.

> still hear the signal in the receiver then you know you were kidding
> yourself. Been there and done that!

A-yup. You did notice the part about the half-dozen loops of wire on a board, around some tacks, right? I could put a microphone on that old Eico, tweak up some sort of an antenna, and have an AM/CW QRP rig on about any HF band. It drifts like a son-of-a-gun without an hour or so warm-up, but it's at least reliably got -something- coming out the leads.

> 4. These old Heath and Eico rf sig gens are good for troubleshooting a
> dead receiver, but not very useful for calibration and alignment work.
> No accurate step attenuator and very leaky.

That's all I've used it for, to date. Splitting the receiver for troubleshooting, for instance, on one of those old AA-5 receivers. Don't really expect it to be much good for anything more, but I do want to use it as well as it can be used.

> 5. As you know receiver noise is the hiss you hear out of the speaker

Brownian noise, intergalactic hiss, whatever you like to call it. It's noise, and there should be less of it with the antenna grounded to the chassis but it's not significantly lower.

> Het, VFO, and Product detector. If this noise level you are
experiencing is a recent
> thing then may have a problem with Mixer stage?

It could still be a problem with the mixer(s), that is where I'm starting anyway. I've been on that section of the service guide and schematic and user's manual.

> 6. One way average ham can evaluate his TS520SE is if you have a analog
> VTVM with dB scales. Here is procedure:

THIS is what I was hoping you'd get to. I couldn't find this procedure when I started searching for it, and I -knew- there was a way to use a decibel scaled meter for a go/no-go sort of test. Not all that definitive, but it's a fantastic way to sort out which direction to go. I will get into this tomorrow, if things go well at the doctor's office. My wife is having some tests, and I expect her to be a bit on the groggy side afterwards, which will leave me free to putter in the shack for several solid hours.

I've presently got a LONG-WIRE out the basement and up a tree. It will be replaced with a G5RV once the temperatures here get back above freezing for substantial parts of the day. Presently it's minus seven C (that's about 20 or 21 Fahrenheit, I think) and it's supposed to drop to minus fifteen or so tonight, still air temp, and with the wind chill it is predicted to be minus twenty-five or so. I'm NOT stringing home-brew ladder line and 70-meter-long dipole legs with that kind of wind chill, the long-wire will have to suffice for now.

(I'm running it through the Versatuner III, and then to the 520. Trying to tune up a long-wire with just the internal pi section of the rig would be a recipe for failure, and maybe even new tubes.)

> The service manual around page 43 has the RX Level Diagrams in it. This

I think it's page 41, I've been living on that page, and the schematic sections, for some days now. I really AM trying not to be a knob about this, though I am not exactly making such a good job of it, am I? Told you getting that Extra license scared the crap out of me. I don't like being caught out in a real storm of stupid.

> how I can help. Need a calculator with anti-log or use log and 2nd key.
> Very easy. If I can do it anyone can.

I used to do it on a slipstick. Probably couldn't do that any more, but my calculator does inverse- or anti- logs.

Actually, that dime hadn't dropped, truthfully, but as soon as I read that it made really perfectly good sense. AGC would tend to change the results, now wouldn't it?

> Absent a calibrated RF Sig Gen and AF VTVM not possible to run RX level
> diagrams.

Got the VTVM. Got the RF probes on the bench being built. The VTVM is pretty well calibrated. I took it to the Engineering building and used one of their calibrated high-precision meters and got it pretty close.

Would LOVE a calibratable signal gennie.

Got a specific model you're partial to? I'm apparently in the market.

> and still need good step attenuator.

It's sitting at the shop, the guy who designed and built the kit (N2APB), has it in his shop again, to get my obviously-ham-fisted surface-mount soldering job into something like working order. I apparently got three of four of the input channels on the first go, but channel four (V-sub-r) isn't making any sense to the CPU yet. I think there's either a bad SMD capacitor on there, or possibly a solder bridge or lifted trace from over-heating.

What I'm talking about is:

http://midnightdesignsolutions.com/micro908/index.html

one of these. Beats an MFJ model, actually, specifications compared to each other, and it seems to be a reasonable and fairly-accurate standard. It should be back here in a few days, maybe a week, or two maximum. I'm going to keep on mucking with antennas at the moment, and work on building up some of my bench tools. I've got a local ham friend who has a decent generator I can borrow, I'll talk to him over the weekend if he's in the area.

If he can loan it to me, I'll get started sooner, but otherwise I'll be waiting for that Micro908 analyzer/signal generator to get back here for my permanent bench set-up.

And I'll be using the VTVM decibel measurement ball-park procedure in your previous post to get more familiar with where everything is inside the chassis. After the power supply and rectifier troubles I had in the early goings, I got quite comfortable with working on and around those boards (rectifier, HV doubler, etc.). The other parts - RF, mixer, etc., are still terra incognita in too many ways. Time for more schematic and layout studying. Doubt that will change for some time.

Wes:

One question:

I am still not clear if receiver was ever "normal" in your possession?

Do I understand that the receiver noise level was "normal" until you did the rectifier board repair? If so, refresh me on what repair you made. I seem to recall you were looking for original diodes at one time, but do not remember the extent of damage on the board and exactly what repairs you made.

No voltages high enough to be producing corona. If HV had carbon path suspect should see that on HV panel meter with unstable indication and wouldnt last very long before failure. Perhaps a bad/loose board ground?

Might put your O-scope on the 14vdc output. Also, look at 14vdc input to AVR board and the 9vdc output from the AVR board.

Terry,

Before plugging in the finals I checked final voltages once again and was puzzled by what I found.

In RX bias is – 110 VDC on the terminal –C of the rectifier board and – 100 VDC on terminal FG of the AF board and on terminal FG and pin 5 on the final unit board. The reason for the drop in voltage is not quite clear to me.

Still in RX bias can be adjusted from – 100 VDC to – 90 VDC with the bias pot metre, but in TUNE mode with SEND flipped bias runs only between – 75 VDC and – 30 VDC. Before it ran up till – 100 VDC.

Even more worrying is the drop of screen voltages. On terminal 210A and 210B on the rectifier board there are 252 VDC, but on terminal SG on the final unit board there are only – 54 VDC in RX mode with the SG SWITCH off and 120 VDC with the SG SWITCH on. On terminal PD1, PD2 and SG1 on the rectifier board there are 54 VDC on each and zero on SG1.

Peter:

C8 is an RF bypass capacitor. Its performance or failure would not be related to tube arc over or tube thermal run away events.

It is extremely difficult to make a solenoid wound Plate choke that will present an acceptably high amount of inductive reactance across the frequency range of our KW hybrids without having a series resonant hole in it close to one of our bands. Adding 160 meters to the transceivers made it even harder to design an effective choke. Couple of options. 1. Use space wound choke to break up the distributed capacitance or 2. Add an additional choke at cold end and orient it at a right angle to break up the mutual inductance coupling. KW chose method 2 as space winding means a much taller choke.

L2 Plate Choke is there to allow us to supply 900vdc anode voltage to the 6146 finals and prevent RF current from flowing back to the HV power supply. The HV filter caps wont like RF. In addition to not wanting ripple on our DC supply it will cause dielectric heating and over time can damage the HV filter capacitors.

L2 is approx 168uhy with a parallel resonant point at approx 14.0 mhz. This means it will have the highest inductive reactance around 20 meters ie it will function best there to provide the highest inductive reactance (opposition to rf current flow). Its first series resonant hole is around 25mhz which is almost too close to comfort for 24mhz operation as that means it will have the lowest inductive reactance and less opposition to RF current flow.

Since L2 cannot offer high reactance across the entire operating range there will always be some RF current that will get past it. We place C8 at "cold end" of the choke to shunt any RF that makes it past L2s windings to ground. C8 has to be a Type 1 capacitor designed for RF current. It is essentially in severe duty.

It is not uncommon to see it discolored, have hole blown in it, and/or the case split open. Always good to inspect it when working on PA cage and as you discovered measuring the capacitance is not an effective way to assess its condition.

Having not witnessed your event and only going on my understanding of what you described it clearly sounds like thermal runaway due to loss of -dc operating bias voltage which is not related to the damage you see on C8.

Who knows maybe you had thermal runaway accompanied by an arc over? If elements sagged could have actually contacted and shorted as opposed to anode voltage ionizing the gas and conducting to the beam plates in the typical manner.

Terry K9TW

Peter,

I don't want to interfere with you and Terry, just thought I would say a few words about your voltage measurements.

First, the Rectifier Unit's "210A" terminal is the driver and both final tube screen power supply "output". The Rectifier Unit's "210B" is not the screen supply's output, it's the output of the screen supply's "rectifier" voltage that is applied to the capacitive input filter on the IF unit. The Rectifier Unit's "210A" and "210B" terminals can be confusing until you trace the wiring on the schematic to the IF Unit's plug 14 pins 1 and 3 and back to the Rectifier Unit. The driver and both final tube screen supply is a half wave rectifier feeding a capacitive input PI filter. The rectifier is D6, C181 (22ufd 350VDC) and C180 (22ufd 350VDC) radial lead capacitors, with R11, 470 ohm resistor connected between C180 and C181's positive terminals. It's a very simple none regulated half wave DC screen supply for the driver and both final tubes.

Next, with the MODE switch set to TUNE, the "210A" output voltage is applied to the Rectifier Unit's relay "RL1" then to the voltage divider resistors R15 and R16, both are 56K 1/2 watt. The voltage at the junction of R15 and R16 is then applied to the Rectifier Unit's "TUNE" terminal which is then applied to the MODE switches "TUNE" terminal. The TUNE voltage is then applied over the "SG1" wire to the Rectifier Unit's "SG1" terminal where it flows through L1 and out PD2 to the Final Unit's "SG" terminal.

Here is how the TUNE mode reduces the final tube screen voltage by 50%. For example, lets say the 210A screen supply output voltage is "+265VDC" and the MODE switch is set to TUNE. The 210A voltage is applied to the voltage divider resistors R15 and R16 through the Rectifier Unit's relay RL1 resulting in approximately .00236 amps of current flowing through both R15 and R16 (265 / 112000 = .00236). This result in a voltage drop across R15 of approximately +132.5VDC (.00236 x 56000 = 132.5) resulting in +132.5VDC at the junction of R15 and R16. The "+132.5VDC" is then applied to the Rectifier Unit's "TUNE" terminal, then to the MODE switch TUNE terminal, through the MODE switch wiper and back through the "SG1" wiring to the Rectifier Unit's "SG1" terminal, through L1, out PD2, to the Final Unit's "SG" terminal then to the 6146 screens. This 50% decrease in screen voltage to the final tube is how the DC input power is reduced in TUNE mode. The final tube screen voltage is reduced in TUNE mode but not the driver tube's screen voltage.

The SG switch, when set to "OFF", will energize the Rectifier Unit's relay RL1. If the relay does not energize with the SG switch set to OFF then check for 12VDC at the AF Unit's "12" terminal.

You said you measured 52VDC at the Rectifier Unit's "PD1, PD2, and SG1" terminal but then you said you measured 0VDC at "SG1". You can't have 52VDC and 0VDC on the SG1 terminal at the same time.

46809. greetings for the new year

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-03 22:12:09 UTC
From: Joseph Stiles
Topic: 46809 Message: 46809

Greetings Group!

Well, we've made it into 2014! The past year has seen many changes, people have left, people have joined, and we've had some "administrative changes" too! All in all, we're doing a pretty good job ofkeeping these fine Kenwoods functioning. I want to thank out in the open the following group members for "Elmering," "mentoring," or any other term you care to attach, and just putting up with those of us that are less learned:
Terry-k9tw(complete explanations of why/how things function), Mike-w5rkl(tnx fer the videos and explanation(s), along with Terry) Gordon-n6wk (for maintaining your web site...and for being there when needed). There are others that also have contributed their knowledge/experience regarding electronics in general, and Kenwood hybrids specifically, your assistance/help is also appreciated!

So, especially for the newer members: the "files section" has tons of info that will more than likely contain info regarding your rigs problem(s). Please, take some time to do your research prior to posting a question. This not is meant to discourage you from asking questions...but sometimes...the question(s) have already been asked and possibly answered. If you are still unsure..feel free to ask.

The Co-owners and moderators...believe it or not..do sleep...and have other "stuff" to do, so if you are a newer member.. or otherwise "moderated", please understand that we try our best to review your posts as quickly as possible and, if appropriate, "approve" them to be sent the the groups main message area.

So...that's it...thanks for your attention...a wonderful 2014 to you all ...hey...it can only get better!

Mike:

You are not interfering. You were originally working with Peter and should continue to do so.

I only got involved with Peter when he was talking about doing my protection mod and was asking about if thought the finals were damaged and should he use them again.

I did not feel that he and certainly me understood the root cause of the event. I was leaning toward thermal run away.

I wanted him to understand if he did not have a good operating bias voltage that the protection mod would not help. It is designed to address arc over from anode to beam plates and not thermal runaway events.

I previously provided my opinion about using the finals over again. If he knows the root cause of the failure then couple of different answers. Arc over does not always damage the tubes. Some people will try the finals again and frequently they will be just fine. I did it one time and couple of days later popped cathode resistors again so I dont trust them and would not use them over.

If root cause was thermal runaway in my opinion much more likely that the finals have been damaged due to elements sagging and contacting. Clearly would not use these again.

I understand he had to pay approx two to three times what we would for same tubes stateside and why he would like to use them again if he could.

The last response I had to Peter was to be 125% certain that he had a good smooth operating bias voltage adjust pot and could set the voltage to approx -60vdc before installing finals.

So unless Peter needs some help regarding the protection mod I would prefer that you would pick back up and work with him.

46811. Reports of poor audio on 830

Yahoo group: TS-520_820_530_830 (2014)

Hello and Happy New year all. Been looking and trying to see if any other posts or articles were on the subject of poor transmit audio. I have a stock TS-830S with the MC-50 mic. Changing from hi to lo Z does have some change and also turning the processor on does make some difference too, but many complain of no bass and all highs in my transmit audio. I also have a Yaesu FT-847 and using the stock hand mic get better audio reports talking to the same station(s). Most have said the 830 is noted for its super transmit audio and WAV files sent to me from other stations do in fact sound tinny. Wondering if any internal adjustments are available? I typically have the processor at about 12 o'clock postion and the mic gain at about 3 o'clock. Any help appreciated. Thank you.

Emne: Re: SV: SV: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

I don't want to interfere with you and Terry, just thought I would say a few words about your voltage measurements.

First, the Rectifier Unit's "210A" terminal is the driver and both final tube screen power supply "output". The Rectifier Unit's "210B" is not the screen supply's output, it's the output of the screen supply's "rectifier" voltage that is applied to the capacitive input filter on the IF unit. The Rectifier Unit's "210A" and "210B" terminals can be confusing until you trace the wiring on the schematic to the IF Unit's plug 14 pins 1 and 3 and back to the Rectifier Unit. The driver and both final tube screen supply is a half wave rectifier feeding a capacitive input PI filter. The rectifier is D6, C181 (22ufd 350VDC) and C180 (22ufd 350VDC) radial lead capacitors, with R11, 470 ohm resistor connected between C180 and C181's positive terminals. It's a very simple none regulated half wave DC screen supply for the driver and both final tubes.

Next, with the MODE switch set to TUNE, the "210A" output voltage is applied to the Rectifier Unit's relay "RL1" then to the voltage divider resistors R15 and R16, both are 56K 1/2 watt. The voltage at the junction of R15 and R16 is then applied to the Rectifier Unit's "TUNE" terminal which is then applied to the MODE switches "TUNE" terminal. The TUNE voltage is then applied over the "SG1" wire to the Rectifier Unit's "SG1" terminal where it flows through L1 and out PD2 to the Final Unit's "SG" terminal.

Here is how the TUNE mode reduces the final tube screen voltage by 50%. For example, lets say the 210A screen supply output voltage is "+265VDC" and the MODE switch is set to TUNE. The 210A voltage is applied to the voltage divider resistors R15 and R16 through the Rectifier Unit's relay RL1 resulting in approximately .00236 amps of current flowing

through both R15 and R16 (265 / 112000 = .00236). This result in a voltage drop across R15 of approximately +132.5VDC (.00236 x 56000 = 132.5) resulting in +132.5VDC at the junction of R15 and R16. The "+132.5VDC" is then applied to the Rectifier Unit's "TUNE" terminal, then to the MODE switch TUNE terminal, through the MODE switch wiper and back through the "SG1" wiring to the Rectifier Unit's "SG1" terminal, through L1, out PD2, to the Final Unit's "SG" terminal then to the 6146 screens. This 50% decrease in screen voltage to the final tube is how the DC input power is reduced in TUNE mode. The final tube screen voltage is reduced in TUNE mode but not the driver tube's screen voltage.

The SG switch, when set to "OFF", will energize the Rectifier Unit's relay RL1. If the relay does not energize with the SG switch set to OFF then check for 12VDC at the AF Unit's "12" terminal.

You said you measured 52VDC at the Rectifier Unit's "PD1, PD2, and SG1" terminal but then you said you measured 0VDC at "SG1". You can't have 52VDC and 0VDC on the SG1 terminal at the same time.

Emne: RE: SV: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter:

C8 is an RF bypass capacitor. Its performance or failure would not be related to tube arc over or tube thermal run away events.

It is extremely difficult to make a solenoid wound Plate choke that will present an acceptably high amount of inductive reactance across the frequency range of our KW hybrids without having a series resonant hole in it close to one of our bands. Adding 160 meters to the transceivers made it even harder to design an effective choke. Couple of options. 1. Use space wound choke to break up the distributed capacitance or 2. Add an additional choke at cold end and orient it at a right angle to break up the mutual inductance coupling. KW chose method 2 as space winding means a much taller choke.

L2 Plate Choke is there to allow us to supply 900vdc anode voltage to the 6146 finals and prevent RF current from flowing back to the HV power supply. The HV filter caps wont like RF. In addition to not wanting ripple on our DC supply it will cause dielectric heating and over time can damage the HV filter capacitors.

L2 is approx 168uhy with a parallel resonant point at approx 14.0 mhz. This means it will have the highest inductive reactance around 20 meters ie it will function best there to provide the highest inductive reactance (opposition to rf current flow). Its first series resonant hole is around 25mhz which is almost too close to comfort for 24mhz operation as that means it will have the lowest inductive reactance and less opposition to RF current flow.

Since L2 cannot offer high reactance across the entire operating range there will always be some RF current that will get past it. We place C8 at "cold end" of the choke to shunt any RF that makes it past L2s windings to ground. C8 has to be a Type 1 capacitor designed for RF current. It is essentially in severe duty.

It is not uncommon to see it discolored, have hole blown in it, and/or the case split open. Always good to inspect it when working on PA cage and as you discovered measuring the capacitance is not an effective way to assess its condition.

Having not witnessed your event and only going on my understanding of what you described it clearly sounds like thermal runaway due to loss of -dc operating bias voltage which is not related to the damage you see on C8.

Who knows maybe you had thermal runaway accompanied by an arc over? If elements sagged could have actually contacted and shorted as opposed to anode voltage ionizing the gas and conducting to the beam plates in the typical manner.

Peter,

Are you sure you measured the Rectifier Unit's "PD1, PD2, and SG1" voltage correctly? You show the Rectifier Unit's PD1, PD2, and SG1 voltage as "half" of the Rectifier Unit's SG2 voltage which is +252VDC. There's noting between the Rectifier Unit's SG2 terminal voltage (+252VDC) and the Rectifier Unit's "SG1" and "PD2" terminals that will cause a 50% drop in DC voltage.

I don't know if an external VFO is constructed the same as an internal VFO.....
I bought an internal 820 VFO just to take one apart.
From what I garner here, the most prevalent problem with VFO is the mechanical electrical connection at the back end of the variable capacitor.
I just dismantled the cap and rebuilt it to like new condition. It will go into the next 820 I work on, maybe today.
There was about 1/32" end play from front to back in the cap.
There was a gap between the phosphor bronze spring at the back and the shaft shoulder it should make electrical connection to.
While originally tempered with a strong arch, that went bye bye long ago.

There is a single ball bearing at the back, it appears to have been greased originally. The grease had contaminated the grounding point at the shoulder on the shaft.
I see the same gap and contamination in the VFO of the 820 I'm presently working on (when I have time). It will be pulled and the rebuilt will go in.
Repeated "spraying and praying" removed none of this, in either VFO.
I believe I have solved the variable cap problem for a long period of continued function.

It is a real pain however getting the VFO out and dismantling the internals and taking the cap apart.
Putting it back together is tricky, the shaft bearings being the biggest challenge.
So, if external VFO is the same as internal VFO
"Spray and Pray".

Mike,

After I had you answer, I measured the PD1, PD2, and SG1 voltages once again. Miraculously the 50 % drop in DC voltage had disappeared! But my joy was short lived. After I had checked bias in the final unit in TUNE mode with SG SWITCH on and SEND flipped, PD1, PD2, and SG1 voltage were 50 % down as before. RL1? D12?

Peter,

Are you sure you measured the Rectifier Unit's "PD1, PD2, and SG1" voltage correctly? You show the Rectifier Unit's PD1, PD2, and SG1 voltage as "half" of the Rectifier Unit's SG2 voltage which is +252VDC. There's noting between the Rectifier Unit's SG2 terminal voltage (+252VDC) and the Rectifier Unit's "SG1" and "PD2" terminals that will cause a 50% drop in DC voltage.

Peter,

I don't want to interfere with you and Terry, just thought I would say a few words about your voltage measurements.

First, the Rectifier Unit's "210A" terminal is the driver and both final tube screen power supply "output". The Rectifier Unit's "210B" is not the screen supply's output, it's the output of the screen supply's "rectifier" voltage that is applied to the capacitive input filter on the IF unit. The Rectifier Unit's "210A" and "210B" terminals can be confusing until you trace the wiring on the schematic to the IF Unit's plug 14 pins 1 and 3 and back to the Rectifier Unit. The driver and both final tube screen supply is a half wave rectifier feeding a capacitive input PI filter. The rectifier is D6, C181 (22ufd 350VDC) and C180 (22ufd 350VDC) radial lead capacitors, with R11, 470 ohm resistor connected between C180 and C181's positive terminals. It's a very simple none regulated half wave DC screen supply for the driver and both final tubes.

Next, with the MODE switch set to TUNE, the "210A" output voltage is applied to the Rectifier Unit's relay "RL1" then to the voltage divider resistors R15 and R16, both are 56K 1/2 watt. The voltage at the junction of R15 and R16 is then applied to the Rectifier Unit's "TUNE" terminal which is then applied to the MODE switches "TUNE" terminal. The TUNE voltage is then applied over the "SG1" wire to the Rectifier Unit's "SG1" terminal where it flows through L1 and out PD2 to the Final Unit's "SG" terminal.

Here is how the TUNE mode reduces the final tube screen voltage by 50%. For example, lets say the 210A screen supply output voltage is "+265VDC" and the MODE switch is set to TUNE. The 210A voltage is applied to the voltage divider resistors R15 and R16 through the Rectifier Unit's relay RL1 resulting in approximately .00236 amps of current flowing through both R15 and R16 (265 / 112000 = .00236). This result in a voltage drop across R15 of approximately +132.5VDC (.00236 x 56000 = 132.5) resulting in +132.5VDC at the junction of R15 and R16. The "+132.5VDC" is then applied to the Rectifier Unit's "TUNE" terminal, then to the MODE switch TUNE terminal, through the MODE switch wiper and back through the "SG1" wiring to the Rectifier Unit's "SG1" terminal, through L1, out PD2, to the Final Unit's "SG" terminal then to the 6146 screens. This 50% decrease in screen voltage to the final tube is how the DC input power is reduced in TUNE mode. The final tube screen voltage is reduced in TUNE mode but not the driver tube's screen voltage.

The SG switch, when set to "OFF", will energize the Rectifier Unit's relay RL1. If the relay does not energize with the SG switch set to OFF then check for 12VDC at the AF Unit's "12" terminal.

You said you measured 52VDC at the Rectifier Unit's "PD1, PD2, and SG1" terminal but then you said you measured 0VDC at "SG1". You can't have 52VDC and 0VDC on the SG1 terminal at the same time.

Peter,

If the SG1 and PD2 voltages drop by 50% with the MODE switch set to TUNE, that's what they are suppose to do. That's how the KW hybrids reduce the final amplifier's DC input power by 50% in TUNE mode.

Therefore, if the Rectifier Unit SG1 and PD2 voltages drop 50% with the MODE switch set to TUNE with the transmitter keyed but increases by 50% back to +252VDC with the MODE switch in USB or LSB mode then the voltage reduction you are seeing in TUNE mode is correct. If you remember I said that the screen voltage is "reduced" by 50% in TUNE mode in order to reduce the final amplifier's DC input power by 50%.

Does this make sense? It's important that you understand what is happening with the SG1/PD2 final tube screen voltage between TUNE and USB/LSB modes.

Peter,

Do this simple voltage measurement.

Leave the SEND switch DOWN, you do not have to key the transmitter for the following voltage measurement.

Make sure the SG Switch is in the ON position, connect your DC volt meter to the Rectifier Unit's "PD2" terminal and rotate the MODE switch to USB, LSB, and CW modes. Note the DC voltage in all 3 positions of the MODE switch, it should be approximately +252VDC.

Do not disconnect the DC volt meter from the "PD2" terminal. Change the MODE switch to TUNE and you should see the volt meter display a "50%" drop in the "PD2" voltage, dropping to approximately +126VDC. The 50% drop in the "PD2" voltage with the MODE switch set to TUNE is how KW reduces the final amplifier's DC input power in TUNE mode.

Peter,

You misunderstood me. What I said was that SG1 and PD2 voltages on the rectifier unit were + 252 VDC with SG SWITCH on. But after having been in TUNE mode voltages didn□t return to +252 VDC, but to +128VDC with SG SWTICH on and to -54 VDC with SG SWITCH off, i.e. a drop of 50 % in STAND BY mode. This is where the radio on power up.

Peter,

If the SG1 and PD2 voltages drop by 50% with the MODE switch set to TUNE, that's what they are suppose to do. That's how the KW hybrids reduce the final amplifier's DC input power by 50% in TUNE mode.

Therefore, if the Rectifier Unit SG1 and PD2 voltages drop 50% with the MODE switch set to TUNE with the transmitter keyed but increases by 50% back to +252VDC with the MODE switch in USB or LSB mode then the voltage reduction you are seeing in TUNE mode is correct. If you remember I said that the screen voltage is "reduced" by 50% in TUNE mode in order to reduce the final amplifier's DC input power by 50%.

Does this make sense? It's important that you understand what is happening with the SG1/PD2 final tube screen voltage between TUNE and USB/LSB modes.

Peter,

Are you sure you measured the Rectifier Unit's "PD1, PD2, and SG1" voltage correctly? You show the Rectifier Unit's PD1, PD2, and SG1 voltage as "half" of the Rectifier Unit's SG2 voltage which is +252VDC. There's noting between the Rectifier Unit's SG2 terminal voltage (+252VDC) and the Rectifier Unit's "SG1" and "PD2" terminals that will cause a 50% drop in DC voltage.

Peter,

I don't want to interfere with you and Terry, just thought I would say a few words about your voltage measurements.

First, the Rectifier Unit's "210A" terminal is the driver and both final tube screen power supply "output". The Rectifier Unit's "210B" is not the screen supply's output, it's the output of the screen supply's "rectifier"

voltage that is applied to the capacitive input filter on the IF unit. The Rectifier Unit's "210A" and "210B" terminals can be confusing until you trace the wiring on the schematic to the IF Unit's plug 14 pins 1 and 3 and back to the Rectifier Unit. The driver and both final tube screen supply is a half wave rectifier feeding a capacitive input PI filter. The rectifier is D6, C181 (22ufd 350VDC) and C180 (22ufd 350VDC) radial lead capacitors, with R11, 470 ohm resistor connected between C180 and C181's positive terminals. It's a very simple none regulated half wave DC screen supply for the driver and both final tubes.

Next, with the MODE switch set to TUNE, the "210A" output voltage is applied to the Rectifier Unit's relay "RL1" then to the voltage divider resistors R15 and R16, both are 56K 1/2 watt. The voltage at the junction of R15 and R16 is then applied to the Rectifier Unit's "TUNE" terminal which is then applied to the MODE switches "TUNE" terminal. The TUNE voltage is then applied over the "SG1" wire to the Rectifier Unit's "SG1" terminal where it flows through L1 and out PD2 to the Final Unit's "SG" terminal.

Here is how the TUNE mode reduces the final tube screen voltage by 50%. For example, lets say the 210A screen supply output voltage is "+265VDC" and the MODE switch is set to TUNE. The 210A voltage is applied to the voltage divider resistors R15 and R16 through the Rectifier Unit's relay RL1 resulting in approximately .00236 amps of current flowing through both R15 and R16 (265 / 112000 = .00236). This result in a voltage drop across R15 of approximately +132.5VDC (.00236 x 56000 = 132.5) resulting in +132.5VDC at the junction of R15 and R16. The "+132.5VDC" is then applied to the Rectifier Unit's "TUNE" terminal, then to the MODE switch TUNE terminal, through the MODE switch wiper and back through the "SG1" wiring to the Rectifier Unit's "SG1" terminal, through L1, out PD2, to the Final Unit's "SG" terminal then to the 6146 screens. This 50% decrease in screen voltage to the final tube is how the DC input power is reduced in TUNE mode. The final tube screen voltage is reduced in TUNE mode but not the driver tube's screen voltage.

The SG switch, when set to "OFF", will energize the Rectifier Unit's relay RL1. If the relay does not energize with the SG switch set to OFF then check for 12VDC at the AF Unit's "12" terminal.

You said you measured 52VDC at the Rectifier Unit's "PD1, PD2, and SG1" terminal but then you said you measured 0VDC at "SG1". You can't have 52VDC and 0VDC on the SG1 terminal at the same time.

Peter,

This is a shot in the dark because i can't see anything that would cause the SG1 voltage not to return to +252VDC when moving the MODE switch from TUNE to USB, LSB, or any of the CW positions. There's nothing I can see that can cause this problem.

Recreate the problem where the SG1 voltage is +128VDC in USB, LSB, or any CW position. Once that happens, leave the volt meter connected to the SG1 terminal then tap on the Rectifier Unit's RL1 relay. If the voltage returns to +252VDC then the Rectifier Unit's RL1 relay is the source of your problem.

Topic: 46806 Message: 46821

Finished putting my rebuilt VFO back together.
That spring is now clean, coated with Corrosion X and has enough bend to it to "SNAP" back when I push on it with one of my butchered dental tools. Bearings a lubed with fine white lithium grease.
All contact surfaces are thoroughly stainless brush cleaned and scuffed up.
Should give many years of trouble free use. I'm hoping that's all that was wrong with the used 820 VFO I bought. A precursor check of diodes on it's board looks like it's OK.
Fingers crossed.
Also just finished my "through hole solder connection" repair.
Not so difficult as just tedious.
My biggest obstacle was getting the old solder out. While solder wick works, it only works so well.....so I tried cleaning the holes to get them big enough with a small pin vise and a .04" drill bit.
Works OK but I pushed one foil loose on the other side.
I was debating getting out one of my Foredom flex shaft tools, I have both the cheaper and the expensive models. Didn't want to spend the 20 minutes to dig that out and set it up.

I'll be putting the rebuilt VFO and the solder repaired board into a 820S later, maybe today, maybe not. Think maybe I'll do some code for awhile, my speed needs work.
Getting the itch to get all the bugs out of my 830S. I think I'll pull her out later. Also just got a new good looking base for my like new J. H. Brunkle & Co. brass key my GF gave me for Christmas. Need to find some appropriate brass screws and make up a cord for it.
You'd think it was just made. Still has the original varnish dip on it!
She found it in an antique store, $10.....I'd like to see the fight over one on eBay!!
Makes me want to use only hand key, but I still have my Novice key from 42 years ago sitting here, I think she'd get jealous.
OK, I'm waffling.
Have a Super new year gentlemen.
Time for a break!!

I don't know if an external VFO is constructed the same as an internal VFO.....
I bought an internal 820 VFO just to take one apart.
From what I garner here, the most prevalent problem with VFO is the mechanical electrical connection at the back end of the variable capacitor.
I just dismantled the cap and rebuilt it to like new condition. It will go into the next 820 I work on, maybe today.
There was about 1/32" end play from front to back in the cap.
There was a gap between the phosphor bronze spring at the back and the shaft shoulder it should make electrical connection to.
While originally tempered with a strong arch, that went bye bye long ago.

There is a single ball bearing at the back, it appears to have been greased originally. The grease had contaminated the grounding point at the shoulder on the shaft.
I see the same gap and contamination in the VFO of the 820 I'm presently working on (when I have time). It will be pulled and the rebuilt will go in.
Repeated "spraying and praying" removed none of this, in either VFO.
I believe I have solved the variable cap problem for a long period of continued function.

It is a real pain however getting the VFO out and dismantling the internals and taking the cap apart.
Putting it back together is tricky, the shaft bearings being the biggest challenge.
So, if external VFO is the same as internal VFO
"Spray and Pray".

Do you have the Service Manual? If not need to down load it. I dont know what Side band you are talking about, but you have two carrier oscillators that need to be adjusted. These oscillators are located on the PLL board and you can access the trimmer capacitors thru two holes in the bottom cover. You can adjust these for a more bass sound or a more communications audio presence. It is sort of a user preference adjustment. The trimmers are sensitive and can drift off over time. TC-2 is adjusted for LSB and TC-3 is adjusted for USB.

Remember where ever you adjust them in Rx mode is how you will sound in Tx mode and vice versa. The Service Manual describes the adjustment under Step 30 SSB Frequency Response. You need an audio oscillator, AF VTVM to measure accurate audio oscillator output level, a wattmeter, and a dummy load to perform this method. You are adjusting TC-2 and TC-3 for 3dB roll off (1/2 half power) at 300hz and 2700 hz. Some do this at 400 hz and 2600 hz.

If you do not have this test gear several other ways to adjust:

1. Use the Marker signal/S-meter method described in the maintenance section of the Survival guide. Step 8.4 on Page 27. This works pretty well. Make sure you place AGC in fast position.

2. Download Spectro-gram audio spectrum analyzer soft ware. This works best if you have a diode noise generator, but can be done by just tuning to a clear frequency.

Make sure the IF shift is in center position for any method you use.

Some people actually just adjust each trimmer by ear and listen to self on Moni.

If adjusting the Carrier Oscillator trimmers dont give you a more bass response come back for more help.

I forgot to mention seldom use the Processor unless chasing some DX and trying to break a pile up running barefoot and never run mic gain more than 1200 on any mic I own.

If I run the processor my mic gain using a Shure 444D is no more than 1100 (#4) and Processor Compression level no more than 1100 and I never use more than approx 10-12 db of compression. With a MC-50 or MC-60 can run mic gain up to 1200 to 1300 but no more.

This all depends on how well your radio has been aligned. There is a transmit ALC alignment and a Speech Processor alignment. May be ok but dont know how many fingers been in the rig.

I would not be messing with the Processor or changing Mic impedance until I had aligned both Carrier Oscillators.

If you have problems getting the old solder out of the through holes, apply new solder to the hole then remove the solder with wick or solder sucker. The old solder should now come out much easier.

From: Peter Ravn
Topic: 46257 Message: 46826

Mike,

I made a mistake by measuring the SG1 and PD2 voltages in TUNE mode and not in CW, USB or LSB mode. That□s the result of working late under stress. As far as voltages is concerned, things now work as they should do.

This morning I installed the 6146B set that turned red due to thermal runaway. Bias was adjusted to 60 ma, and in TUNE mode with the meter on ALC I could peak DRIVE, but in TUNE mode with the meter on RF, the needle didn□t move at all when I turned the PLATE control. Therefore I expected the old 6146□s to have gone bad because of the thermal runaway event.

Then I tried the new 6146W set that arced over when I first installed them. The same happened as before. When setting the bias in USB/LSB mode to 60 ma, there was a flash. The only difference was that the cathode resistors did not open due the K9TW cathode resistor protection modification. Thank you, Terry! The diodes did their job and survived the arcing over.

Finally I tried a completely new set 6146B with exactly the same result as the first one mentioned.

Preliminary conclusion: The old red 6146B set seems to work, though possibly with reduced power. The new 6146W set is definitely bad and will be returned to the seller.

But why no PLATE reading on the panel meter in TUNE mode with the meter on RF and SEND flipped? I replaced the 12BY7A driver tube, but it had no effect. Can the first arcing event have caused serious damage somewhere else? I have done the final cage repair kit mod, so the problem must be somewhere else.

Peter,

This is a shot in the dark because i can't see anything that would cause the SG1 voltage not to return to +252VDC when moving the MODE switch from TUNE

to USB, LSB, or any of the CW positions. There's nothing I can see that can cause this problem.

Recreate the problem where the SG1 voltage is +128VDC in USB, LSB, or any CW position. Once that happens, leave the volt meter connected to the SG1 terminal then tap on the Rectifier Unit's RL1 relay. If the voltage returns to +252VDC then the Rectifier Unit's RL1 relay is the source of your problem.

Mike W5RKL

On 1/4/2014 1:40 PM, Peter Ravn wrote:

Peter,

You misunderstood me. What I said was that SG1 and PD2 voltages on the rectifier unit were + 252 VDC with SG SWITCH on. But after having been in TUNE mode voltages didn□t return to +252 VDC, but to +128VDC with SG SWTICH on and to -54 VDC with SG SWITCH off, i.e. a drop of 50 % in STAND BY mode. This is where the radio on power up.

Peter,

If the SG1 and PD2 voltages drop by 50% with the MODE switch set to TUNE, that's what they are suppose to do. That's how the KW hybrids reduce the final amplifier's DC input power by 50% in TUNE mode.

Therefore, if the Rectifier Unit SG1 and PD2 voltages drop 50% with the MODE switch set to TUNE with the transmitter keyed but increases by 50% back to +252VDC with the MODE switch in USB or LSB mode then the voltage reduction you are seeing in TUNE mode is correct. If you remember I said that the screen voltage is "reduced" by 50% in TUNE mode in order to reduce the final amplifier's DC input power by 50%.

Does this make sense? It's important that you understand what is happening with the SG1/PD2 final tube screen voltage between TUNE and USB/LSB modes.

73
Mike W5RKL

On 1/4/2014 12:24 PM, Peter Ravn wrote:

Mike,

After I had you answer, I measured the PD1, PD2, and SG1 voltages once again. Miraculously the 50 % drop in DC voltage had disappeared! But my joy was short lived. After I had checked bias in the final unit in TUNE mode with SG SWITCH on and SEND flipped, PD1, PD2, and SG1 voltage were 50 % down as before. RL1? D12?

Peter,

Are you sure you measured the Rectifier Unit's "PD1, PD2, and SG1" voltage correctly? You show the Rectifier Unit's PD1, PD2, and SG1 voltage as "half" of the Rectifier Unit's SG2 voltage which is +252VDC. There's noting between the Rectifier Unit's SG2 terminal voltage (+252VDC) and the Rectifier Unit's "SG1" and "PD2" terminals that will cause a 50% drop in DC voltage.

bias

Peter,

I don't want to interfere with you and Terry, just thought I would say a few
words about your voltage measurements.

First, the Rectifier Unit's "210A" terminal is the driver and both final tube screen power supply "output". The Rectifier Unit's "210B" is not the screen supply's output, it's the output of the screen supply's "rectifier" voltage that is applied to the capacitive input filter on the IF unit. The Rectifier Unit's "210A" and "210B" terminals can be confusing until you trace the wiring on the schematic to the IF Unit's plug 14 pins 1 and 3 and back to the Rectifier Unit. The driver and both final tube screen supply is a half wave rectifier feeding a capacitive input PI filter. The rectifier is D6, C181 (22ufd 350VDC) and C180 (22ufd 350VDC) radial lead capacitors, with R11, 470 ohm resistor connected between C180 and C181's positive terminals. It's a very simple none regulated half wave DC screen supply for the driver and both final tubes.

Next, with the MODE switch set to TUNE, the "210A" output voltage is applied to the Rectifier Unit's relay "RL1" then to the voltage divider resistors R15 and R16, both are 56K 1/2 watt. The voltage at the junction of R15 and R16 is then applied to the Rectifier Unit's "TUNE" terminal which is then applied to the MODE switches "TUNE" terminal. The TUNE voltage is then applied over the "SG1" wire to the Rectifier Unit's "SG1" terminal where it flows through L1 and out PD2 to the Final Unit's "SG" terminal.

Here is how the TUNE mode reduces the final tube screen voltage by 50%. For example, lets say the 210A screen supply output voltage is "+265VDC" and the MODE switch is set to TUNE. The 210A voltage is applied to the voltage divider resistors R15 and R16 through the Rectifier Unit's relay RL1 resulting in approximately .00236 amps of current flowing through both R15 and R16 (265 / 112000 = .00236). This result in a voltage drop across R15 of approximately +132.5VDC (.00236 x 56000 = 132.5) resulting in +132.5VDC at the junction of R15 and R16. The "+132.5VDC" is then applied to the Rectifier Unit's "TUNE" terminal, then to the MODE switch TUNE terminal, through the MODE switch wiper and back through the "SG1" wiring to the Rectifier Unit's "SG1" terminal, through L1, out PD2, to the Final Unit's "SG" terminal then to the 6146 screens. This 50% decrease in screen voltage to the final tube is how the DC input power is reduced in TUNE mode. The final tube screen voltage is reduced in TUNE mode but not the driver tube's screen voltage.

The SG switch, when set to "OFF", will energize the Rectifier Unit's relay RL1. If the relay does not energize with the SG switch set to OFF then check for 12VDC at the AF Unit's "12" terminal.

You said you measured 52VDC at the Rectifier Unit's "PD1, PD2, and SG1" terminal but then you said you measured 0VDC at "SG1". You can't have 52VDC and 0VDC on the SG1 terminal at the same time.

Ron

Go to the Schematic to identify its function.

All pots are labeled as "VR" such as VR-1 or VR-3.

If it is an off board pot it will have the VR designator along with the function name beside it. For example CAR LEVEL is VR-2.

Trim pots on the boards do not have the function name only the VR designator and ohmic value. For example the S-meter span pot on the IF board is VR-1 10k.

I know of no pot called or labeled the "AF Voltage" pot? AF means Audio Frequency and the only pots I am familiar with related to the AF board are the AF gain (speaker volume) and the Side Tone Osc volume.

Peter,

That's good and it settles a few questions that kept puzzling me. For safety sake, never work on a radio when you are tired, you can make some serious mistakes that can harm you.

You said you can peak the drive, good ALC indication in TUNE mode, with the 6146Bs installed so, for now, that eliminates the driver tube. The symptoms did not change by replacing the driver tube. Always look at the meter indications and the symptoms before changing any component or tube. If there is plenty of drive indicating strong ALC indication then the driver tube is fine and no need to replace it.

Have you checked the rear panel's RF VOLT pot setting? The RF VOLT pot controls the RF indication with the meter switch set to RF. There is no meter scale for the RF meter switch setting. The RF meter switch setting displays "relative" output and there is no meter scale for the RF meter switch setting, simply follow the RF VOLT pot setting instructions in the operator's manual.

What is the IP meter indicating when the transmitter's adjusted for maximum power output?

What is the HV meter indicating when the transmitter's adjusted for maximum power output?

You should also measure the final tube screen and cathode voltages when the transmitter's adjusted for maximum power output.

Lets assume the cathode resistance is approximate 5 ohms and the IP meter is indicating 225ma, the final tube cathode voltage, measured at pin 1 of the final tube socket, should be approximately +1.125VDC. The final tube's screen voltage, measured at the final unit's "SG" terminal, should drop from +252VDC down to approximately +210VDC. The HV should drop from approximately +900VDC down to approximately +825VDC. Measuring the final tube's screen, cathode, and looking at the HV meter indication with the 830 keyed in CW mode (CW key removed from the rear panel CW socket) will tell you a lot of what's happening in the final amplifier. That's why it's important to check these voltages in both standby and transmit.

If the 6146Ws are still arcing, throw them away so you don't accidentally put them in by mistake in the future.

Hi All
As I have now got my full uk ticket and changed my email address accordingly I have rejoined the group. My experience on the technical side is limited but I am very willing to learn. I run an ts-520se which gets me very good reports and also have 2 ts-830s rigs both of which have various problems, the one I am working on suffers from very low output on ssb and I have tried various mics including the one from my 520 all with similar results. The output on cw seems fine. I have been sitting on the sidelines following with interest all relevant posts and would appreciate any help given.

finally a happy new year to all in the group

Mike,

You did not say "how" you were monitoring the 830's RF output in sideband transmit. We need to know whether you are using the 830's RF switch setting or a watt meter.

If you are using the 830's RF meter switch setting, have you looked at the rear panel's RF VOLT pot? Review the operator's manual on how to set the RF VOLT control.

If you are using a watt meter, you did not states what the watt meter was indicating when operating side band with the MIC gain set between 10 and 11 o'clock.

I forgot to ask whether you have and are using a 50 ohm dummy load or an antenna to test the 830's power output in sideband? If you do not have a 50 ohm dummy load I recommend you obtain one and use it for testing.

There are numerous 50 ohm "dry" (no oil) dummy loads. A few example are the Vectronics VEC-552 (1.5KW), MFJ-260C (300 watt), and the MFJ-264 (1.5KW). The MFJ-260C will work with the KW hybrids but the key down period, at 100 watts output, must be kept to a maximum of 1.5 minutes followed by a 2 minute cool down period. I use the MFJ-260C on the work bench and keep key down periods to less than 30 seconds. I use the VEC-552 as the station dummy load, works very well with 100 watt exciters and 600 watt amplifier (AL-811). I personally don't care for the oil filled dummy loads, too messy for my taste.

As I said, you should get into the practice of using a 50 ohm dummy load when testing/troubleshooting exciters and even tuning transmitters when changing frequencies. Keep unnecessary interference off the air plus provides a stable 50 ohm "non-inductive resistive load" to the transmitter.

Mike,

Okay, try using the 830's RF meter switch setting to see if there is any indication of output power.

Also, after you tune the transmitter up, following the transmitter tuning procedures in the operator's manual, set the meter switch to RF then set the rear panel RF VOLT control to the middle of its travel and test transmitter in SUB or LSB. Let us know what the RF meter shows.

Mike,

My 830S is on the air again. Once again you were right, Mike. I had overlooked the RF volt pot setting at the rear panel. After almost three weeks I have had the first QSO□s with good audio reports. Neutralisation of the new 6146□s remains, but will be done soon.

Thanks a lot you and Terry (K9TW). You are running an absolutely first class casualty department for those lost in the wood.

[TS-520_820_530_830] TS830S no bias

Peter,

That's good and it settles a few questions that kept puzzling me. For safety sake, never work on a radio when you are tired, you can make some serious mistakes that can harm you.

You said you can peak the drive, good ALC indication in TUNE mode, with the 6146Bs installed so, for now, that eliminates the driver tube. The symptoms did not change by replacing the driver tube. Always look at the meter indications and the symptoms before changing any component or tube. If there is plenty of drive indicating strong ALC indication then the driver tube is fine and no need to replace it.

Have you checked the rear panel's RF VOLT pot setting? The RF VOLT pot controls the RF indication with the meter switch set to RF. There is no meter scale for the RF meter switch setting. The RF meter switch setting displays "relative" output and there is no meter scale for the RF meter switch setting, simply follow the RF VOLT pot setting instructions in the operator's manual.

What is the IP meter indicating when the transmitter's adjusted for maximum power output?

What is the HV meter indicating when the transmitter's adjusted for maximum power output?

You should also measure the final tube screen and cathode voltages when the transmitter's adjusted for maximum power output.

Lets assume the cathode resistance is approximate 5 ohms and the IP meter is indicating 225ma, the final tube cathode voltage, measured at pin 1 of the final tube socket, should be approximately +1.125VDC. The final tube's screen voltage, measured at the final unit's "SG" terminal, should drop from +252VDC down to approximately +210VDC. The HV should drop from approximately +900VDC down to approximately +825VDC. Measuring the final tube's screen, cathode, and looking at the HV meter indication with the 830 keyed in CW mode (CW key removed from the rear panel CW socket) will tell you a lot of what's happening in the final amplifier. That's why it's important to check these voltages in both standby and transmit.

If the 6146Ws are still arcing, throw them away so you don't accidentally put them in by mistake in the future.

73
Mike W5RKL

On 1/5/2014 5:44 AM, Peter Ravn wrote:

Mike,

I made a mistake by measuring the SG1 and PD2 voltages in TUNE mode and not in CW, USB or LSB mode. That□s the result of working late under stress. As far as voltages is concerned, things now work as they should do.

This morning I installed the 6146B set that turned red due to thermal runaway. Bias was adjusted to 60 ma, and in TUNE mode with the meter on ALC I could peak DRIVE, but in TUNE mode with the meter on RF, the needle didn□t move at all when I turned the PLATE control. Therefore I expected the old 6146□s to have gone bad because of the thermal runaway event.

Then I tried the new 6146W set that arced over when I first installed them. The same happened as before. When setting the bias in USB/LSB mode to 60 ma, there was a flash. The only difference was that the cathode resistors did not open due the K9TW cathode resistor protection modification. Thank you, Terry! The diodes did their job and survived the arcing over.

Finally I tried a completely new set 6146B with exactly the same result as the first one mentioned.

Preliminary conclusion: The old red 6146B set seems to work, though possibly with reduced power. The new 6146W set is definitely bad and will be returned to the seller.

But why no PLATE reading on the panel meter in TUNE mode with the meter on RF and SEND flipped? I replaced the 12BY7A driver tube, but it had no effect. Can the first arcing event have caused serious damage somewhere else? I have done the final cage repair kit mod, so the problem must be somewhere else.

TS830S no bias

Peter,

This is a shot in the dark because i can't see anything that would cause the SG1 voltage not to return to +252VDC when moving the MODE switch from TUNE to USB, LSB, or any of the CW positions. There's nothing I can see that can cause this problem.

Recreate the problem where the SG1 voltage is +128VDC in USB, LSB, or any CW position. Once that happens, leave the volt meter connected to the SG1 terminal then tap on the Rectifier Unit's RL1 relay. If the voltage returns to +252VDC then the Rectifier Unit's RL1 relay is the source of your problem.

73
Mike W5RKL

On 1/4/2014 1:40 PM, Peter Ravn wrote:

Peter,

You misunderstood me. What I said was that SG1 and PD2 voltages on the rectifier unit were + 252 VDC with SG SWITCH on. But after having been in TUNE mode voltages didn□t return to +252 VDC, but to +128VDC with SG SWTICH on and to -54 VDC with SG SWITCH off, i.e. a drop of 50 % in STAND BY mode. This is where the radio on power up.

TS830S no bias

Peter,

If the SG1 and PD2 voltages drop by 50% with the MODE switch set to TUNE, that's what they are suppose to do. That's how the KW hybrids reduce the final amplifier's DC input power by 50% in TUNE mode.

Therefore, if the Rectifier Unit SG1 and PD2 voltages drop 50% with the MODE switch set to TUNE with the transmitter keyed but increases by 50% back to

+252VDC with the MODE switch in USB or LSB mode then the voltage reduction you are seeing in TUNE mode is correct. If you remember I said that the screen voltage is "reduced" by 50% in TUNE mode in order to reduce the final amplifier's DC input power by 50%.

Does this make sense? It's important that you understand what is happening with the SG1/PD2 final tube screen voltage between TUNE and USB/LSB modes.

Mike,

After I had you answer, I measured the PD1, PD2, and SG1 voltages once again. Miraculously the 50 % drop in DC voltage had disappeared! But my joy was short lived. After I had checked bias in the final unit in TUNE mode with SG SWITCH on and SEND flipped, PD1, PD2, and SG1 voltage were 50 % down as before. RL1? D12?

Peter,

Are you sure you measured the Rectifier Unit's "PD1, PD2, and SG1" voltage correctly? You show the Rectifier Unit's PD1, PD2, and SG1 voltage as "half" of the Rectifier Unit's SG2 voltage which is +252VDC. There's noting between the Rectifier Unit's SG2 terminal voltage (+252VDC) and the Rectifier Unit's "SG1" and "PD2" terminals that will cause a 50% drop in DC voltage.

Peter,

I don't want to interfere with you and Terry, just thought I would say a few words about your voltage measurements.

First, the Rectifier Unit's "210A" terminal is the driver and both final tube screen power supply "output". The Rectifier Unit's "210B" is not the screen supply's output, it's the output of the screen supply's "rectifier" voltage that is applied to the capacitive input filter on the IF unit. The Rectifier Unit's "210A" and "210B" terminals can be confusing until you trace the wiring on the schematic to the IF Unit's plug 14 pins 1 and 3 and back to the Rectifier Unit. The driver and both final tube screen supply is a half wave rectifier feeding a capacitive input PI filter. The rectifier is D6, C181 (22ufd 350VDC) and C180 (22ufd 350VDC) radial lead capacitors, with R11, 470 ohm resistor connected between C180 and C181's positive terminals. It's a very simple none regulated half wave DC screen supply for the driver and both final tubes.

Next, with the MODE switch set to TUNE, the "210A" output voltage is applied to the Rectifier Unit's relay "RL1" then to the voltage divider resistors R15 and R16, both are 56K 1/2 watt. The voltage at the junction of R15 and R16 is then applied to the Rectifier Unit's "TUNE" terminal which is then applied to the MODE switches "TUNE" terminal. The TUNE voltage is then applied over the "SG1" wire to the Rectifier Unit's "SG1" terminal where it flows through L1 and out PD2 to the Final Unit's "SG" terminal.

Here is how the TUNE mode reduces the final tube screen voltage by 50%. For example, lets say the 210A screen supply output voltage is "+265VDC" and the MODE switch is set to TUNE. The 210A voltage is applied to the voltage divider resistors R15 and R16 through the Rectifier Unit's relay RL1 resulting in approximately .00236 amps of current flowing through both R15 and R16 (265 / 112000 = .00236). This result in a voltage drop across R15 of approximately +132.5VDC (.00236 x 56000 = 132.5) resulting in +132.5VDC at the junction of R15 and R16. The "+132.5VDC" is then applied to the Rectifier Unit's "TUNE" terminal, then to the MODE switch TUNE terminal, through the MODE switch wiper and back through the "SG1" wiring to the Rectifier Unit's "SG1" terminal, through L1, out PD2, to the Final Unit's "SG" terminal then to the 6146 screens. This 50% decrease in screen voltage to the final tube is how the DC input power is reduced in TUNE mode. The final tube screen voltage is reduced in TUNE mode but not the driver tube's screen voltage.

The SG switch, when set to "OFF", will energize the Rectifier Unit's relay RL1. If the relay does not energize with the SG switch set to OFF then check for 12VDC at the AF Unit's "12" terminal.

You said you measured 52VDC at the Rectifier Unit's "PD1, PD2, and SG1" terminal but then you said you measured 0VDC at "SG1". You can't have 52VDC and 0VDC on the SG1 terminal at the same time.

Peter

Peter:

Glad you got the TS-830 going. Good learning exercise. Hopefully not too expensive.

Regards your JAN 6146W tubes you might try talking to Merit Arnold at RF Parts Company. He is the owner and is a ham and has reputation for being honest business man. Not sure if he takes calls anymore or not.

Glad you didnt pop the cathode meter shunts again when you tried the finals after the arc over event. Absent a DC hipot test it is always a gamble if you try finals again. As I mentioned I dont like exposing my panel meters to the risk. With your diode string installed should limit meter circuit exposure to approx 2vdc.

46837. Kenwood Hybrid Net Update (January 5, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-05 19:37:49 UTC
From: Mark Gilger
Topic: 46837 Message: 46837

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday 40 meter net had 19 stations checking in under noisy band conditions. There were 2 new stations checking in, KK4SWX, and KD4ZCC. We had the following number of radios checking in.

4 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
4 running TS-830S

I was running my TS-830s with an L4B amplifier.

The Sunday□s 20 meter net had 19 stations checking in under good band conditions. There was 1 new stations checking in, AG6DB.

Out of those, there was:

4 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
4 running TS-830S

I was running my 820 twins, TS-820s + R-820.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email.

Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 19, Sunday☐s total = 19 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

You're welcome Peter, that is what this group is all about, providing "factual" technical information to help members get back on the right track to success in fixing their KW hybrid problems and educating the members as well.

Hello Terry an group ,, the question I have is: does it matter if an Allen wrench is used in the tuning coil lugs or do I need to find another tool ??? Thanks

It does a bit, metal tools will affect the tuning and almost certainly crack the fragile ferrite core!

That's not to say I haven't used metal allen keys or screwdrivers on stubborn cores, but only as a second-last resort when the last resort is to smash the buggers out and fit new ones.

Peter:

Glad you got the TS-830 going. Good learning exercise. Hopefully not too expensive.

Regards your JAN 6146W tubes you might try talking to Merit Arnold at RF Parts Company. He is the owner and is a ham and has reputation for being honest business man. Not sure if he takes calls anymore or not.

Glad you didnt pop the cathode meter shunts again when you tried the finals after the arc over event. Absent a DC hipot test it is always a gamble if you try finals again. As I mentioned I dont like exposing my panel meters to the risk. With your diode string installed should limit meter circuit exposure to approx 2vdc.

Ron:

Never use metal tools (screw drivers, allen wrenches etc) to adjust any hex core slugs. A real good way to crack the core.

If you are going to perform KW hybrid work you need to invest in proper alignment tools. K4EAA sells proper AL-1 plastic alignment tool for the TS520 coils for $2.95.

Can buy a GC Waldom set that has common needed tools. They use to sell a 8 piece CB/TV alignment set.

Check on Ebay and Amazon.

I moved my "known to be working correctly" TS-530 across country in my car...carefully. Now when I turn it on the meter pegs to the right on receive. It does this in any position of the band selector, mode selector and meter setting. If I activate the send button on tune or CW it goes to zero on the left and there is no output. It will show HV. SG switch position does not make a difference but I wouldn't expect that it would for receive.

I think that for a minute when I was in the tune position, send button on and the meter in ALC I could use the drive control but no joy at present. Nothing

The TS-820 restore is shaping-up nicely so far. It now receives and the digital display now works. Just two more issues to solve outside of the gain drop after transmit. Although it does transmit fine LSB and USB, it doesn't on CW. When placed in the "Tune" or "CW" mode and advancing the "Carrier" level control on the front panel, no output is observed. Just a few more things to sort out.

Bob:

Been years since I owned a tube tester. Had several Hickok units over the years. At one time I did some TV repair and just about anyone who did that had a tube tester. Some used neon lamp and others used an megohm scale on the GM meter to indicate shorts. I prefer to measure parameters rather than see a lamp glow. Not sure what it is telling me. Would always do shorts test first and leakage tests. Would switch between different combinations of elements and if got brite glow of the neon lamp or unacceptable resistance reading would trash the tube and no reason to look at the Gm. As I recall they were particularly good for looking for heater to cathode leakage.

So I am not a tube tester expert and dont own one now. However, if you own a tube tester and have had a 6146 final that has gotten so hot that anode glowed cherry red it is possible that other elements have deformed and could indicate as shorted on your tester. Might even show up with standard ohm meter test using a VOM or DMM just not much voltage pushing any current. I am just not a big fan of using a 6146 over again that has experienced thermal run away. I have seen couple of rigs that tubes got so hot that the glass envelope actually softened and sucked in due to the differential between atmosphere and vacuum.

If we are talking 6146 arc over then tube tester wont be much help. Arc overs dont usually result in element damage as the event is short lived and usually confined to the anode and beam plates. I believe the arc is due to off gassing and the ionizing of that gas. Others think may be foreign material or a "wisker" protruding in the gap between anode and beam plates. A DC Hi-pot would be instrument of choice so you could run a stepped dc test up to approx 2000vdc to 2500vdc and measure the micro ampere leakage. With 6146 we are talking under 50ua and usually closer to 10 to 15 ua of leakage. Could use a Meggar and read the leakage in meg-ohms, but most meggars have fixed voltages of 250 or 500 or 1000vdc. I have seen a 5kv meggar (even motor operated so you dont wear out your arm cranking while charging up long runs of cable), but generally the voltage is not continually variable to use for tube testing. More for power cable insulation testing and motor winding polarization index etc. If you were to use a Meggar just have to convert from megohm to ua for meaningful results. 10 ua leakage at 2000vdc is same as 200meg ohm.
Transmitter engineers would be more likely use to seeing leakage expressed in terms of ua as opposed to meg ohms.

I have heard of people charging up a capacitor on there linear amp Anode supply and using it to "pop" transmitter tubes in lieu of a dc hi-pot. I dont recommend this for obvious reasons!

Short answer is if you have a tube tester go ahead and use the Shorts test function to check a 6146 that has runaway. I just dont know how meaningful the results will be. What would be an acceptable resistance? To me a new tube should read infinite between control grid and screen grid for example. I would think any glow of the Shorts lamp would be basis to reject the tube. I guess could compare against known good tubes.

Kevin,

For this simple voltage test, leave the HEATER switch OFF, SEND switch DOWN, VOX turned OFF, Mode switch to USB or LSB, and power up the 530. Measure the DC voltage at plug 6 pin 6 on the AF Unit board. The voltage, in receive, should be "0VDC". If you measure approximately +12VDC on AF Unit plug 6 pin 6 then Q12 on the AF Unit board may be shorted Emitter to Collector causing the relay to energize in receive.

Diode D10 between Q12's collector and ground on the AF Unit board could also have failed. D10 is a protection diode that keep the collapsing magnetic field that occurs in RL1's relay coil when power to the relay is removed, from damaging Q12 (switching from xmit to rcv).

D10, a 1S1555, is a silicon diode which can be replaced with a 1N4003 diode.

An NTE-290A is a possible replacement transistor for Q12 if Q12 is found to be defective.

Terry: Thanks for the prompt and informative reply.

My feeling is that having a traumatic experience such as thermal run away MIGHT leave some indication that a quality GM tube tester MIGHT pick up..anything other than "normal" on any of the tests..in the trash!? I would test for any used tube in any service, audio or RF. I agree that If tests are normal, still taking a chance after a thermal....

For various reasons, I still have tube testers....between 10 - 15 at last count!

From: Karl Schwab
Topic: 46857 Message: 46857

A ham friend of mine bought a brand new TS-820 when they were first introduced and used it for a few years and then bought a solid state radio. The '820 remained unused from that point on and remains in his well kept basement (dry/clean) as I write this. He offered this radio to me for free this week as he decided that he has no further interest in ever using it and that I could use it and keep it at my son's farm so I don't have to drag my transceiver back and forth. The '820 was in perfect working condition when he last used it.

What precautions should I take before I plug the '820 in the wall? I have a variac, dummy antenna, and years of experience in using tube-type radios. I am sure that this topic has been discussed before, and if I could be directed to it, that would be great.

Thanks to all for your help and comments; de KO8S, Karl

Hi Mike
I have done as you suggested and the results as follows
 After tuning up set rf volt control to middle of its travel
Whistled into mic on usb about 10% deflection in rf position
swapped to lsb and repeated test and got about 12% deflection
Just to get a benchmark in cw full scale deflection.
Then I tried pressing the proc button and lo and behold the power came up to about 50% deflection and when I switched it off again power stayed up but on repeating this test several times results varied wit both on and off positions giving good and poor results.
Dont know if this helps identify the problem but suspect there is a problem in that area.
Being dyslexic I am not so good at following the diagrams but am trying to understand how the circuit works.

Mike,

Okay, try using the 830's RF meter switch setting to see if there is any indication of output power.
Also, after you tune the transmitter up, following the transmitter tuning procedures in the operator's manual, set the meter switch to RF then set the rear panel RF VOLT control to the middle of its travel and test transmitter in SUB or LSB. Let us know what the RF meter shows.

Mike,
using the instructions you gave, in the rec position (down) I got 0 volts. If I put the position in the send position I got 11.3VDC. I assumed I was supposed to leave plug 6 in place and "back pin" wire 6 for the voltage reading.

Of course after I run the test the radio now acts normally except....when I get it cranked up to about 40 watts in the Tune position the relative RF meter goes full scale. If I pump it up to 100 watts it pegs.

My first problem caused by me having the RF know burned down was operator error for certain. I can't imagine what I am going to cause this. I also know that I was not imagining the radio putting out power in both Send and Rec, but I guess for the moment that is over.

It sounds like yours hasn't broken yet, might put a gob of blue locktite on it and it'll snug up as that dries.
Deforming the round shape would help more threads to engage and hold too, i.e. make it more square than round and loctite that bugger.

Yes, Kevin, leave the plug in place when measuring the voltage on plug 6 pin 6.

Check the RF VOLT pot, it may be set too high. The RF VOLT adjustment is

I mean no disrespect Kevin so please don't take this the wrong way. The meter's RF setting is controlled by the rear panel RF volt pot (RF Meter) setting. This control is referred to as "RF VOLT" or "RF METER", depending on the operator's manual. This control, regardless of what label it has, does exactly the same thing, rectifies a sampling of the RF output converting it into a DC voltage. The amount of DC voltage that is applied to the RF meter is controlled by the RF VOLT pot. This simple circuit can be seen on the Hybrid's schematic.

I take the buggers out and replace them with a standard SO-239 and 2 steel pop rivets. Nice and tight and the will not come loose. I use the panel mounts without the nut on the end of a coax to tie to the short piece of coax on the antenna. Then I don't have to bring down all the coax to repair an antenna. Also if you got to a music like Guitar Center and ask them to order you some of the lock nuts for a microphone stand you have the same thread.

Craig:

Are you seeing the regulated 9vdc varying at TP-6?

If so, I dont understand how RF-1 would not also be varying proportionally as well?

If you are measuring it at VFB then you may have a dirty mini-din switch in the external VFO connector on rear panel of rig. I clean with deoxit and exercise with a din plug.

Can also be a dirty FIX switch. Try exercising it.

Hi Dave:

As you know the connector is a "D" hole. It is designed for Bulk Head SO-239 connectors.

Most folks do not have or do not fabricate a spanner wrench for the Japanese nut that KW used. They typically resort to tightening the nut using pliers or channel locks or vise grips and usually end up doing the ham-fisted approach of deforming the nut. Seen this a lot and sure dont want any of these back yard mechanics touching any of my radios.

As you know the hole is the standard "D" hole to key the connector to prevent body rotation. You can buy a nice amphenol or american brand D hole bulkhead connector that comes with a nice shoulder on the outside and is secured with an inside star lock washer and heavy hex nut on the inside face of the rear panel. Problem is you cannot get a 6 point socket on this nut as one side of the nut flats is too close to the lip of the back panel. So you need to tighten with an open end wrench which can round off the nut if not careful. They make a special bulk head wrench for this. Sort of like a flat flare nut wrench.

I have installed quite a few "D" thru hole bulk connectors on customer rigs and I use the serrated star lock washer and a little locktite and have no problems after that. I have them on both my daily driver TS-830s.

You can use the standard 4 hole mount connector but you need to drill out the D hole inorder for this connector to lay completely flat against the back panel. Also no room to install the two sets of hardware on the side closest to the back panel lip so would have to use rivets.

I have seen a couple installs where the fellow installed the common 4 hole panel mount connector and didnt drill out the D hole and the connector is cocked on an angle and not flush against the panel and secured with two rivets on diagonal corners. Another ham-fisted cobble job.

It all depends on your idea of craftsmanship and quality. I guess why we have Macys and why we have Walmart. Customer always defines quality.

If I were you I would purchase couple of quality thru hole D mount (Bulkhead) connectors and try them. DX Engineering sells a Bulk Head Wrench or with the metal fab skills that I know you possess can make a nice tight fit flat stock wrench with a slight angle on the handle.

Terry K9TW.

Dave:

I forgot to mention the stock DX Engineering wrench does not work well on the inside of the rear panel due to the edge lip interference, but it does work well on the outside if you replace the stock slotted nut. However a good 6 point socket works as well. A two jaw close tolerance flat wrench is what you need for inside hex nut tightening.

Thanks, Terry.

I did measure the wavering 9V at TP6. I was alerted to the problem of a "warbling" VFO -- especially notable on CW -- after replacing the AF board with a spare*. I did the star washer and extra ground lead installations, for whatever they're worth, so the often mentioned glitchy ground(s) on the AF board is probably not the problem.

* The original board was rife with cracked traces from the Molex headers, most likely due to some rough handling by a former owner. This radio as received by me showed other signs of ham-fisted service, such as the use of non-standard fasteners, including a wood screw (!), in several places. I have put a lot of work into this radio and am left only with this one, annoying anomaly to correct. I have noted a factory approved mod calling for 22K resistors to be added between the collectors and emitters of Q30 and Q34 to improve regulator stability, but the voltage excursion I am experiencing seems too excessive and faulty to respond to that.

I have encountered several of the loose SO-239 connectors on the 530 and 830 radios. I have found that a 17mm box end wrench fits the strange nut used by Kenwood. The nut can be tightened very tight using this wrench and does not bugger up the nut. I have not had one come loose after tightening in this manner.

Craig:

OK I got confused and responded direct to your email.

For others who are interested there is no reason to place 22k resistors in shunt with the series pass transistors. The TS-520 and TS820 use a 68 ohm and 150 ohm series pass shunt resistors for couple of reasons: 1. To allow them to use a cheaper lower rated series pass transistor by sharing the load and 2. To provide for reliable regulator start up by providing some output voltage for the reference voltage stage.

KW changed design with 530/830 and no need for a shunt resistor across the series pass devices.

No reason to do the star lock washer or extra ground wire mod. Thousands of rigs in service operating just fine without doing this mod. Wont hurt, but wont fix VFO problem. Another case of confused cause and effect. Be very wary of performing any of these "KW mods".

What does the 12vdc do? Can you monitor 9vdc and 12vdc with analog voltmeters at same time?

Also, have you tried cleaning and running VR-4 voltage sampler pot thru its range mulitple times?

Could be a bad solder connection?

Dick:

Maybe we can talk about soldering some time. I often open up a rig to perform a good visual inspection and have to look up to see if a pigeon is flying overhead!

All too common to see solder balls and flash on the boards and chassis not to mention globs upon globs and cold solder joints. The 520s with point to point final socket wiring gets pretty ugly.

Old days local clubs taught soldering to budding Novices with simple projects like code practice oscillators.

Havent looked at You Tube. Maybe there are some good tutorials there?

Just another old mans pet peeve. See it in lots of places in todays world for what passes as workmanship. Problem is apprentice no longer learns trade under tutelage of master craftsman. Not only technique and tricks of the trade were taught, but pride in workmanship was instilled and trades and companies had written standards that had be adhered to.

No hammers or vice grips on my RF bench yet! I do have a 200 watt iron (great for PL-259), but I think I finally threw away the acid core solder!

46879. 6146 Arc Over Protection Mod

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-08 20:30:28 UTC
From: <wagstw46@...>
Topic: 46879 Message: 46879

I am writing this to give some added details to my 6146 arc over protection mod that Mark Gilger posted on WB4HFN site. Several people have communicated with me to report they have installed the mod of recent and I just saw a picture today of the neat install that Craig Roberts did on his TS-830. This prompts me to provide these reminders.

1. Do not substitute resistors for the Ohmite Type OY glitch resistors unless the subs are specifically designed to withstand high energy surge current. For example do not install a traditional rectangular sand body power resistor. There are different schools of thoughts about a "glitch" resistor. Some folks want them to be sacrificial and open the anode supply with fault current. That may be OK in grounded grid triode tube amps, but not with a tetrode. We dont want that. We are simply adding some resistance to the HV secondary to limit the fault current to a lower value than just the 5 ohms of cathode meter shunt resistance. With a tetrode we dont want to "fuse" the anode voltage with the screen grid energized as we would damage the finals by exceeding the screen grid dissipation.

2. Some have asked about increasing the value of the resistors. Yes you could go a little higher. However, we do not know the exact total HV secondary resistance (ESR). I would use 250ma for sizing calcs. With 10 ohms at 250ma you are dropping approx 2.5vdc across the resistors at about .6 watts dissipation. At 20 ohms dropping approx 5.0vdc at about 1.25 watts dissipation. Some had asked about using 50 ohms based on seeing this value in high power linears. Remember in this service seeing 2500vdc to 3500vdc anode voltage and far more joules of energy delivery from the filter caps. Suggest you read Eimac Bulletin 17 that does a good job of addressing glitch resistor sizing.

3. Safety Caution: Remember by adding the glitch resistor terminal strip away from the HV filter caps that you have added a new place in the radio for accidental contact with 900vdc.

4. Some people are installing a lexan shield around the glitch resistors to contain the resistors in event of catastrophic failure to contain the shards of ceramic material. This is OK, but again there should be no failure of that kind with these resistors. Could be that kind of failure if you use a different type of power resistor.

5. Craig shortened the MOV leads and heat shrinked them. This is OK.

6. Craig installed the 3 silicon diodes in heat shrink tubing. This is OK. There is no current in normal operation so no heating to worry about and if a diode did pop the heat shrink might contain it.

7. Once again if you install this mod remember it was never intended to protect against thermal runaway. Best protection there is to ensure you have a good clean bias voltage adjust pot.

8. You must understand that there was no dynamic testing of this mod. I did not intentionally jumper 900vdc to the cathode pin of the tube socket to see if the transformer primary fuse would blow and the 5 ohm cathode meter shunt resistors would remain intact. That is what the design is intended to accomplish.

Lastly, I cannot guarantee that your panel meter or other components will not be damaged in the event of future tube arc over events that you may experience post mod installation. Hopefully, the worst you should experience is a blown fuse.

Thanks to those who wrote and shared pictures. I would be most interested in hearing about any experiences you have with post mod arc overs. Hopefully none!

46881. TS-830S 9V supply FIXED

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-08 23:51:00 UTC
From: Craig Roberts
Topic: 46847 Message: 46881

As Terry suggested, VR4 on the AF board -- which controls the 9V power supply output -- was indeed dirty. Some judicious cleaning and exercising of this little trim pot cured my "warbling VFO" problem. The TS-830S's frequency is now free of wild excursions and its normal, steady warm-up drift is nearly absent (fewer than 100 Hz in the first 15 minutes and rock steady in the 45 minutes since).

As is often the case, the causes of our radios' malfunctions are less than catastrophic. This glitch was so simple in its origins that it escaped me (something else that is often the case). I am especially embarrassed in this instance since one of my Drake TR-7s had demonstrated a similar fault. The cause? A dirty trim pot in the radio's low voltage supply!

Thanks again, Terry!

73,

Craig

Craig:

Always nice when you do not have to pull a board. We are lucky that active devices are probably last on the list of root cause of hybrid failures. Speaks to the design and the quality of the devices that KW engineers speced.

This is a very mature series regulator with feedback circuit and pretty trouble free.

A lot of times people rush to replace the reference zener D25 with no good reason. If it shorts then the output voltage will usually go very low perhaps around 1vdc and if its bias current resistor R127 goes open then there will be no regulation. If R127 shorts then likely that D25 will be destroyed.

Even a 3 terminal regulator requires a resistive voltage divider on the output and one of those has to be a trim pot if you want to adjust the output voltage.

Hi group,

I am having very bad vfo drifting and i found that the 9V on the AF1 pin 1 is unstable and when i can see the voltage drifting i also see the signals in my computer drifting the same way.

I read that an option is to change the 2SA496 transistor in the board, but here in Europe its very hard to get them. I found two sources, one from UK other from USA, but both very expensive (for such an item) to be delivered. And after all it may not be the transistor.

Maybe its another problem ? Maybe there are substitutes?

Thanks
LY5AT

Linas,

If you find Q7 on the 820's AF AVR Unit board (2SA496(Y)) is bad/needs to be replaced, let me know, I have a few "new" 2SA496(Y). I also have a few new 1N5234B, 6.2 Volt 1/2 watt zener diode, to replace D5 (WZ-061) on the AF AVR Unit board.Make sure you need Q7 and/or D5 first. No need to replace either one if they are not bad.

I think the NTE374 crosses to the 2SA496Y if that helps..

Q7 could be bad but just guessing at this point. Before you pull the AVR board and replace series pass transistor do one or both of the following:

1. Clean output voltage sample trim pot VR-4 with Deoxit and run thru range several times and blow out with canned air. Reset the voltage at Conn AF-1 to 9.0vdc.

2. Measure/monitor with a DMM the voltage at the cathode of reference zener D5 and at the wiper of output voltage sampler pot VR-4. With wiper at center of range the voltages should be exactly the same and should be very stable. Very easy to access both places on the board. Should see something on order of 5.950vdc to 6.150vdc at both places. Anything around this value as long as both are the same and stable.

The way this thing works is Q1/Q5 are configured as long tail pair differential amp with Q1 serving as emitter follower and Q5 as the gain amp. Together they form a Comparator with zener reference input and output voltage sample input. If there is any slight difference between these two voltages an error voltage is produced. That error signal is amplified by Error amp Q6 and applied to base of series pass Q7 which changes its degree of conduction or series resistance that it offers. If the voltage at wiper of VR-4 is floating around then 9vdc output will follow.

Hello Linas,

Before doing anything else, try cleaning VR4 on the AF board. It is the trimmer that controls the 9V power supply output. At Terry's suggestion, I did this on my TS-830S last night. and it not only cured a continuous VFO instability problem, but reduced overall VFO drift dramatically. My radio is now essentially drift free after about 15 minutes. It is nearly as steady as my TS-530S in which I installed a "huff 'n puff" VFO stabilizer.

73,

Craig

Thank you for responding Mike,

I am not very experienced on this rig, all im able to do is read around and try to to the same as others wrote. In order to test the the transistor should i take it out and measure it with a multimeter or is there another way?

I also tried to exercise the pot that adjusts the 9v voltage, did not seem to help to stabilize it.

Thanks.

Linas,

As I said, replace Q7 and/or D5 ONLY if they are found to be bad. I recommend you follow Terry's advice.

Mike and I work very hard to try to help people to troubleshoot these rigs to find the problem and to replace only parts that are bad and not just "easter egg" or "shot gun" the repair. I missed that he told you to only replace pass transistor and zener reference if found to be bad. Question then becomes how do you make that determination.

Not picking on you but I am beginning to wonder if in some cases it might be faster and easier to have folks just remove the board and replace all the active devices. In the case of an AVR we are talking about 4 transistors and one diode. After all they are 30 to 35 year old devices. If cleaning of connectors and pots do not restore function might be best to just pull board and replace suspect parts? Assumes you want to leave rig in stock config which I recommend.

As to transistor testing several approaches:

1. Take transistor EBC voltages if you can get access to the device leads, but you need to be able to interpret what those readings mean. Have to recognize when BE junction is forward biased, when transistor is saturated etc. Can compare to the voltages noted on schematic but only as a starting point. Not always correct.

2. Can do turn on and turn off tests in circuit, but have to understand transistor lead configuration and be able to get on EBC leads. To turn off transistor need to use mini or micro grabber test leads and jump from Base to Emitter as you monitor Collector voltage. If device is capable of being turned off Collector voltage will rise toward supply. To turn on a transistor use same micro grabber leads and insert a 10k series resistor and jumper from Collector to Base while monitoring Collector voltage and if device can be biased on the voltage will drop. These turn on and turn off test need to be practiced on a bread board to learn how to do it and interpret the results. If can turn a transistor on and off it means it is not shorted or open and will likely work in circuit. Doesnt tell anything about leakage and how well it will work at RF.

3. Can purchase in circuit testers that will work about 75% of the time. The old Sencore Cricket was pretty good. May be better testers today that I am unfamiliar with. Again need to be able to access the transistor leads and not always possible from component side of KW hybrid boards.

4. As you mention can remove device from the board and perform ohm meter back to back testing on all junctions. If you have gone this far might want to just install replacement device?

So again depending on the persons knowledge, experience, and test gear it may be easier and faster to just remove the board and replace the relevant devices.

With experience the AVR board is very easy to power up outside the rig and load test before re-installing back in the rig to verify the new devices fixed the problem.

I am struggling trying to decide what is the best counsel. Of course it varies from person to person.

It sounds like you cleaned VR-4 and saw no improvement. I would like to see voltage at wiper and at reference zener before you pull the board, but that is up to you.

The wholesale replacement of possibly faulty parts without sometimes complex and equipment-necessitating testing is still a step away from the military approach: replace the whole board (or the whole radio).

If circuit board component swapping is anticipated on a regular or semi-regular basis, purchase of a K9TW-endorsed Hakko 808 desoldering kit is highly recommended. As I enthused just after I acquired mine a few days ago -- what a great addition to any tinkerer's shack! I'm having such fun with mine that I am almost hoping for radio problems to crop up. (I suspect I will outgrow this phase shortly, however).

Best of luck, Linas. Keep us posted.

Terry and Linas,

No problem Terry, just wanted to ensure Linas understood that even though I have the original Q7 transistor and 6.2 volt Zener diode for D5 that he should not replace a component without ensuring either component needs to be replaced. As you eluted to Terry, and I agree, all too often people tend to replace a component that is not defective.

Linas, looking at Q7, with the heat sink facing away from you, at the rear of the transistor, the pin labels are from left to right, Emitter, Collector, Base.

Also, Linas, you said you adjusted VR-4 and it made no difference in the 9VDC, I assume you meant at plug AF1 pins 1 and 2 on the AF AVR Unit board. If that's true then either VR-4 is bad or it's very dirty/corroded and the wiper is not making contact with the fixed resistive element on VR4.

Another issue Linas, look closely at VR4, are you sure you are adjusting VR4? VR4 is in the middle of the AF AVR Unit board. It's easy to mistakenly adjust VR3 which is situated close to VR4. VR3 is the CW sidetone input level to the audio amplifier on the AF AVR Unit board. When VR3 is adjusted it raises or lowers the CW side tone you hear in the speaker when operating CW.

Terry

Thank you for all the very useful info, my friend in the Netherlands will help me , if i wont be able to do it myself , realize the tips given here. You got to understand that my electronics knowledge is very basic compared to all of you since i am 17 years old, i read here in the groups that the transistor is usually the thing that causes such drifting vfo instability, that is why it made sense to me to get the transistor and at least try. This being my first and only, donated , rig i want to have it working.

I am not yet doing anything, removing boards or transistors, i will first check maybe its just oxidation on the pot because i didint have anything like deoxit to spray on it. Then i will try to measure the voltages as you said in the previous post.

It did make difference to the actual voltage, not to the stability of it, what is what i wanted to say. I exercised it a couple of times turning it, then i put it back near 9,1v .

Linas:

Sure wish we had a means on this forum where we could Show and Observe as well as Tell.

I remember being 17 believe it or not in 1963! I had been a ham for 3 years and played with electronics since I was about 10 years old. I did not own a sophisticated high performance transceiver like a Kenwood TS-820 and internet did not exist and no technical forums like this one. About best you could do back in that day was go to local ham club and seek help or perhaps if lucky have a close by elmer or mentor.

You will find that with many problems that you encounter with your TS-820 there will be many recommendations to replace a particular component. For example, if you have weak or no receive someone might suggest that you replace the RF amp dual gate mosfet on the RF board. You never want to follow that kind of advice. Well intentioned, but often very misguided.

Make sure you download copy of the 820 service manual if you have not already done so. Also, can get some nice high resolution schematics on K4EAA Website. The circuit descriptions along with the block diagram is good place to start your study.

There is one other thing you can do and that is swap boards. I dont know about availability where you live but stateside easy to buy spare boards. I have spare AVR board but must hang on to it as I service these radios. Also see them on Ebay being parted out.

I think Mike is in better position to help you troubleshoot your AVR board and he apparently has spare parts available. I will monitor and if you get stuck perhaps I can help if needed, but you are in very good hands with Mike.

Topic: 46900 Message: 46900

While preparing my old friend for sale I loaded up into all bands on a dummy. I never used anything but 15 and 20 M when I had it in service. So all bands loaded nicely until I got to 10M. At that point I had trouble getting ALC indication. It would come up grudgingly but then drop to zero almost immediately. No RF output either. What can I check?

Terry,
Have you tried Skype for live help?
Web cams are cheap and the comms are 'free'.
Tablets and i-phones also good.

I would recommend that our friend with the unstable 9V buys some Deoxit-d5, applies a drop and then works the pot.

Dick:

Thanks for that valuable tip. I never tried a 12 point or metric wrench on any. I spent some time fabing a T-handle spanner wrench needlessly!

In addition to the buggered up condition you describe I do find them deformed and stripped and I replace those with Bulk head connectors.

And I told you not learning much anymore. You need to come out of the shadows more often! Suspect much more you could teach this grass hopper!

Thanks

Thanks Terry,

I have an actual KW spanner and a socket that tightens them perfectly with no slipping or rounding of corners. As you know I'm very anal about OEM standards so can't drill the rear panel and be happy. It is only one 830 that is the issue, the thread is good. I have just ordered a couple so hopefully they'll arrive in a few weeks just in time for the radio change over again LOL.

Sure hope your not suffering too must with that Ploar Vortex, didnt they make a movie about that? Think Denis Quaid was in it.

Subject: RE: [TS-520_820_530_830] SO239 panel mount

Hi Dave:

As you know the connector is a "D" hole. It is designed for Bulk Head SO-239 connectors.

Most folks do not have or do not fabricate a spanner wrench for the Japanese nut that KW used. They typically resort to tightening the nut using pliers or channel locks or vise grips and usually end up doing the ham-fisted approach of deforming the nut. Seen this a lot and sure dont want any of these back yard mechanics touching any of my radios.

As you know the hole is the standard "D" hole to key the connector to prevent body rotation. You can buy a nice amphenol or american brand D hole bulkhead connector that comes with a nice shoulder on the outside and is secured with an inside star lock washer and heavy hex nut on the inside face of the rear panel. Problem is you cannot get a 6 point socket on this nut as one side of the nut flats is too close to the lip of the back panel. So you need to tighten with an open end wrench which can round off the nut if not careful. They make a special bulk head wrench for this. Sort of like a flat flare nut wrench.

I have installed quite a few "D" thru hole bulk connectors on customer rigs and I use the serrated star lock washer and a little locktite and have no problems after that. I have them on both my daily driver TS-830s.

You can use the standard 4 hole mount connector but you need to drill out the D hole inorder for this connector to lay completely flat against the back panel. Also no room to install the two sets of hardware on the side closest to the back panel lip so would have to use rivets.

I have seen a couple installs where the fellow installed the common 4 hole panel mount connector and didnt drill out the D hole and the connector is cocked on an angle and not flush against the panel and secured with two rivets on diagonal corners. Another ham-fisted cobble job.

It all depends on your idea of craftsmanship and quality. I guess why we have Macys and why we have Walmart. Customer always defines quality.

If I were you I would purchase couple of quality thru hole D mount (Bulkhead) connectors and try them. DX Engineering sells a Bulk Head Wrench or with the metal fab skills that I know you possess can make a nice tight fit flat stock wrench with a slight angle on the handle.

Terry K9TW.

Dave

It is not being anal to not want to needlessly chop and hack on your radios. I agree would never drill out the stock punched D hole to allow a 4 hole chassis mount connector. Just as I would never mount one that was not flush against the back panel so it rules out the common 4 hole connectors for me.

I just installed much nicer and heavier bulk head connectors on my two 830s. Only a KW hybrid aficionado would notice the difference.

Been around -25C for a week here and 3 foot of snow on the level. Suppose to be 4.5C on Saturday so now folks will have problems with flooded basements as ground is frozen and no place for the melting snow to go. Great fun!

hi,

these fine radios don't like to sit idle, even if you use only a few bands,
please clean the band switches using Deoxit or your favorite brand contact cleaner,
be sure to use the smallest amount and avoid getting the cleaner on the wafers,
they will wick it up.

> LY5AT Linas

A friend of mine (who is not a radio amateur) gave me some information for you.

For "DeOxit D5" you probably want

"Tuner 600" from "Kontakt Chemie"

That should be an equally-good contact and control cleaner spray. DeOxit does not seem to be readily available. My friend uses this "Tuner 600" spray for cleaning guitar amplifier controls. Not quite the same sort of equipment, but the general procedure is the same.

BE SURE TO REMOVE THE POWER FROM THE RADIO! These chemical cleaners can catch on fire quite easily, and you risk getting burned, or burning your radio, or even your whole house. Easy to avoid this, just pull the plug from the mains supply socket.

Use a small amount of the spray applied to the openings you see in the VR-4 control. A little goes a long way. It does not need to flow out like a small river.

While it is still wet inside there, turn the control back and forth several times, through the entire range of motion, nearly a full 360 degrees.

Repeat the process once more, with another small amount of "Tuner 600" spray, and again, rotate the potentiometer from one stop to the other, several times.

The spray will loosen any dirt, corrosion, or other contamination, and turning the control will push it away with the liquid solvent chemicals to wash it off of the moving 'wiper' part of the potentiometer.

After you have done the cleaning procedure two times, spray VR-4 with 'canned air' to push out as much of the liquid "Tuner 600" as you can, and then allow it to sit until it is completely dry.

Do not apply power until the cleaner spray chemicals are all gone, This is to avoid that fire hazard, if there is a spark from a control or

switch when you power the radio back on, it could catch the whole thing on fire. We DO NOT want that. It is just too embarrassing. (Not to mention very expensive to replace a whole house.)

Once it is dry, put it together, plug it back in, and check the voltages. I hope that is all it needs.

Geluk!

Topic: 46883 Message: 46909

VR-4 is an open PC board vertical mount carbon trace trimmer pot. It is not metal can or plastic case enclosed.

No need to spray it at all. Just use couple of small drops of DeOxit D100L using the applicator that comes with it or spray small amount of D5 in a pill bottle and dip artist brush in and transfer drop or two to the trim pot.

After exercising and blowing off with canned air I like to apply couple of drops of DeOxit Fader Type F Lube as it is made for lubricating carbon trace controls. It comes with a needle applicator which lasts much longer than spray.

If DeOxit is unavailable there lots of other brands of contact cleaners that are favorites of repair and restoration folks from various trades as Will suggests.

I have never looked in to availability of Cermet or Metal film trimmers to replace these carbon controls.

1. Did you try with CAR Level pot advanced full CW (should not normally be required on a TS-830)
2. Simple first step is try another 12BY7A driver tube.

3. Try peaking just the 10 meter drive coil on RF board. See page 27 of maintenance section of your operating instruction manual.

If none of this works come back for more help.

Hi firstly I would like to thank everybody who helped me with the Keying problem I had with this radio, after changing Q8 and the relevant diode on the VOX board the PTT and VOX now work as they should.
I now have what appears to be low drive when I go to transmit, I have to have the CAR control at its full setting to get 3/4 Scale deflection on the meter, I have gone through the alignment procedure in the manual on all stages except the balanced modulator, so what I am asking is :-
1 Will the balanced modulator effect the amount of carrier present?
2 Should I be suspect of the Driver valve (This has developed a blue glow on TX)?
The radio is transmitting with an output level of about 85 Watts at 14.175 (Measured into a dummy load)
Many thanks
Peter G8ZZL

46913. TS-830 DDS VFO and panadapter

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-10 14:36:11 UTC
From: <cocobean64@...>
Topic: 46913 Message: 46913

Hello everyone,

Thought I'd share my project as there may be others interested in this as well. It is not 100% completed yet, but looks pretty good up till this point.

I love the older hybrids and also a panadapter function, but since there is no connection pc to radio, the panadapter software is kind of bleh....

What I've done is take some existing ideas (DDS VFO) and "customized" it to suit my needs. The hardware consists of an Arduino micro controller with an AD9850, an encoder,20x4 digital display, a 12 position wafer switch and a couple of toggle and push buttons.LP-Pan 2.

Base software is available on the net and modified accordingly to my taste.

The DDS VFO will supply the VFO signal to the radio (now done by the analog VFO)
Goals are:
Minimal changes to the radio, make it as much "plug and play" as possible.
- Interface the DDS VFO with the PC using NaP3 panadapter software.
- Obtain band information from the radio via extra wafer switch.
- Obtain mode information from the radio
- Obtain Rx/Tx state from the radio

Since we're using a DDS VFO..
- Select VFO A or B
- Work split frequency's
- Point and "click" on the Nap3 software to change frequency.
- The LCD will display the VFO A and or VFO B frequencies, Band info.

- The freq. change rate (when spinning the encoder) can be set manually or automatically.

I've been in contact with Pete F5VNB regarding the Nap3 software as it will require a slight modification. Currently the software wants to connect to a radio, but in my case there is no radio, just a microcontroller that will send and receive data.
Pete is busy but will look into what it takes for same changes.

Where I'm at:
The base "protoype" has been built/programmed and tested and works.Don't have the band switch in yet, nor the split functionality. It controls the radio and sends data to the Nap3 program.
Been on the air with it and have had good reports. As far as birdies or spurs on the VFO signal, I've been monitoring this with my scope but have not seen any.

Topic: 46900 Message: 46914

That the point about "idleness is corrosion's workshop", my current TS-830S was DOA at my doorstep on all bands except 40 meters. The previous owner explained that for the past two decades or so he had used the radio just once a year -- on Field Day weekend -- and only on 40 meters. A careful and thorough cleaning of the blackened band switch revitalized the rig on all bands.

Now, for 10 meter drive and output (presuming band switch cleaning and driver tube replacement don't work and you are getting SOME ALC reading, no matter how low, with the carrier control wide open). here's a trick offered by a prominent KW hybrid tech (I will not name him since this method might be controversial): Tweak not only the Drive coil for maximum ALC indication in "Tune", but the RF (mixer) coil as well. The interaction can work to bring up the drive level significantly. Theoretically, the 10 meter receive level will be degraded a bit this way, but the S/N level supposedly remains steady -- at least to the ear.

I'll be interested to know what our troubleshooting gurus think of this method. If nothing else, it's harmless and instantly reversible.

73,

Craig
W3CRR

Any filter you install in the 830 will also be used in transmit. I realize you only want to "receive AM" but any filter that is installed in the 830 will also be in the "transmit signal path" so it will be used in transmit.

I am not familiar with the filter you are referring to, "CFW 456.5HT". Personally, I would not recommend installing a filter in your 830 just for receiving especially if you also transmit on the hams bands with your 830.

That's the optional AM filter for the TS-830S(M) version that we weren't lucky enough to get in the good ole USA. As shown in Gordon's TS-830S service manual scan, the (M) version had an extra, dedicated circuit board for the mode. The Yaesu hybrids at the time, like the FT-102 and FT-902DM, had AM transmit and receive capability, but our domestic KWs did not. (At least as far as I know).

If I could find an (M) version, I'd snatch it up, even though I suspect it's not true AM.

Incidentally, does anyone have a Yaesu hybrid as a companion to your Kenwood. If so, how do they compare?

Craig,

I have a couple of friends that bleed Yaesu. When I have put any of my 530 or 830s on the bench, side by side to the yaesu, they all agree Kenwood has far better transmit audio and far better receiver, both in sensitivity and selectivity. They do think the Kenwood 20 series has even better receivers.

But there again everytime I go the blood band they have trouble with the large K that comes out of my veins HIHI

Thank Terry,

I hope to get the new panel mounts within 3 weeks. OK on the cold, 35C today and moving to 47C by Thursday, over here. Gives me the opportunity to do start on another 830 restoration on RDO, heat does have its advantage.

Stay warm

Dave

It is not being anal to not want to needlessly chop and hack on your radios. I agree would never drill out the stock punched D hole to allow a 4 hole chassis mount connector. Just as I would never mount one that was not flush against the back panel so it rules out the common 4 hole connectors for me.

I just installed much nicer and heavier bulk head connectors on my two 830s. Only a KW hybrid aficionado would notice the difference.

Been around -25C for a week here and 3 foot of snow on the level. Suppose to be 4.5C on Saturday so now folks will have problems with flooded basements as ground is frozen and no place for the melting snow to go. Great fun!

The VFO on my 530S does not move from frequency to frequency. For example on 80 meters is shows 3.00 and will not move as the knob is rotated. 40 meters is 6.5.. etc.

I was having some output trouble, checked the cathode and screen resistors, buttoned it back up and now have this issue. It MUST be something I did. Looked for loose connectors etc.
Best,
Kevin

Adding just an AM filter will not allow you really receive true AM signals. You also have to disable the product detector and add in some type of AM detector to demodulate the AM signals. In the overall scheme of things, it isn't worth the time, effort, or results. The TS-830S in stock form was designed as a SSB/CW transceiver. Back in the 90's when I talked with one of the Kenwood engineers about adding the additional AM board and 6KHz filter (to make it a TS-830M) to my TS-830S, he indicated it wasn't worth the time or trouble.

Hello again,

I have cleaned the VR4 pot properly, i found a local version of deoxit. The voltage on VR4 is adjusting as it should be, but ifi set 9.00 V , in a minute it will slowly drift to 9.06 or even more, sometimes even more .

On the zener diode i measure a very stable 6.00-6.01 V, no instability here.

I haven't yet checked the transistor, but one thing i noticed that it is so hot on the heatsink that its burns to the touch.

In my opinion the only one that even comes close is the FT-101ZD. Not scientific or AB testing just based on having operated one for awhile.

I use to work on FT-101s and I dont touch them anymore. Far more of them were made and sold and in the hands of CBers and have suffered a lot of operational abuse and hacking. The cosmetic condition is usually far worse. Seen some real beaters.

Some of the design is very similar and some quite different. Service literature is pretty good.

Of course parts rig FT-101s abound at lower cost even ebay auction fever prices are lower. So you should be able to keep your Yaesu going for long time.

I guess it may have something to do with your first transceiver. Some guys bleed Swan others Heath etc. I built HW-101 and it was great fun and had SB-102, but always wanted to upgrade to a KW hybrid. Started with a 520 and lusted for a 830.

They are all fun from this generation, but I wont trade my KW Hybrids. Heck even among hybrid owners there are those who are loyal to a particular model. Typically much debate over 820 vs 830 and which is the better rig.

Ask Jimmy Lamanteer WB2KNR which is his favorite. At last count I think he had 10 or 12 original TS-520 rigs! He just has too much gold!

Linas

Couple of things. You have proved that your zener reference is good.

1. The heatsink will get warm to the touch, but should be able to leave your finger on it. Should never be too hot to touch or leave finger on it. Of course I have calloused old man fingers!

2. It is normal for the 9vdc to drift up a few millivolts from cold start, but should then lock in.

Look at the schematic of the AF-AVR board and you will see R38 68 ohm resistor in shunt with the series pass transistor. This is an old trick from the tube TV set linear regulator power supply days. You probably never seen a console tube TV set. Was a piece of furniture that sat on the floor!

Whenever you have essentially a constant load on a linear regulated power supply you can use a lower rated and lower cost pass transistor by shunting it with a bypass resistor to share the load. This is the case with your 820. The 9vdc load is pretty constant. It is a wasteful design but proven and works well.

In this case R38 will see approx 5vdc IR drop. 5/68 = approx 74ma current. If you pull AF-1 connector and measure from 9vdc output (pin 1 or 2) at the pulled plug to chassis ground with rig down powered should measure something like 86 ohms. 9/86 = 105ma total load on the regulator. So the shunt bypass resistor carries approx 74ma of this load and the pass transistor carries 25ma. So the pass transistor is turned on to look like approx 200 ohm resistor. As long as the load current never goes lower than approx 74ma the thing will regulate.

What this could mean is that it is possible that R38 has drifted high in value or is open and the series pass transistor is forced to carry most if not all of the 105ma load current.

One other possibility is there is a fault on the 9vdc bus (rail) causing additional load current but not as likely.

First thing to do is down power and pull AF-1 and measure the resistance from 9vdc output pins 1 or 2 at the pulled plug to chassis ground to confirm that you have approx 86 ohms. Assuming that is good then you will measure the resistance of R38. Leave AF-1 unplugged and measure from top of R38 to hole where R37 enters the board. You will be directly across R38. It should read very close to 68 ohms. If it is high or open then need to replace it. Replace it with a metal film. Wattage is I^R or .075 x .075 x 68 = 0.38 watts. Use nothing less than a 1 watt resistor. If R38 is good then I would replace the pass transistor.

If you have to remove the board to replace bad R38 you may want to just go ahead and replace the pass transistor.

Linas and Terry,

I don't know what happened to your message Linas, appears it has gotten lost in the Yahoo server. I cut and pasted your message response "text" below:

"/If i did not mix up the legs , Emitter is around 13.50 , varying alot from 13,25 to 13.60 approx//
/
/Collector is 9.01, seems stable on the digital multimeter, but vfo isint as i told here.//
//Base voltage is 12.65 , varying too//
//
/
/The area around the Q7 had alot of this very thick, bubbly goo, maybe its from all the heat during years of time? //
/
/Im adding a picture
//https://www.dropbox.com/s/dnotilf3cw48wvv/2014-01-11%2013.30.27.jpg//
/
/It scraped off a bit .//"/

The "bubbly" coating seen on the picture does appear the heat sink has gotten warmer than it should. The 820 I use to have didn't have that "bubbly" discoloring/coating on the foil side of the AF AVR Unit board. I agree with Terry, check the resistor first and if necessary, replace it. If, however, the resistor is okay, measures within tolerance and you decide to replace Q7, let me know and I'll send you a "new" original 2SA496(Y) transistor.

Plugged out of the board AF1 conenctor pin 1 or 2 to the chasis measures
66.7 ohm , not 86 .

Measuring the R38 shows 67.8 ohms.

Linas

Before someone gives me an F on my report card I forgot that the audio preamp stages on the AVR board are also powered by the 9vdc regulator so after measuring the off board load resistance need to reland AF-1 plug and measure resistance again and should see something on the order of approx 48 to 50 ohms.

This means total load current will be approx 9/48 = 188ma. 188-75 = 113 ma load carried by the series pass transistor and 75ma by shunt bypass resistor.

Sorry about that. Been awhile since I had a TS820 on the bench.

In any event should be able to leave finger on the heat sink.

Well my notes show approx 86 ohms. I have my personal TS-820 here but the covers are on. Perhaps another member has covers off and can quickly check this for you? If not, I can remove covers and do so if needed.

What is resistance from 9vdc pin 1 or 2 to chassis ground with AF-1 plug landed? This should be total of off board and on board load that the regulator will see. My notes show approx 48 to 50 ohms.

I think Mike is correct time to replace Q7. Also, need to take a good hard look at R38 68 ohm bypass resistor while the board is out.

If it were me I would not replace unless I bench tested it first. Very easy to do if you have some resistors to use as dummy loads. If not will just have to re-install to see if it is fixed.

Terry,
I guess I should have explained it better. I took some standard SO 239,s to a friend of mine at the machine shop I use to work at and he matched the flat from the panel mount to the SO 239. Only drilled 2 holes for the pop rivets. It leaves the D stamping intact and only adds 2 - 1/8 inch holes. He did a dozen of them for me. I could grind them but its not as nice job as a milling machine will do. This way you can go back if you desire.

I can clarify that with AF2 AF3 plugged in , AF1 out, pin 1 or 2 to ground measures 65.8 ohm

AF1 and all others plugged IN pin 1-2 is 44.2 ohm

Rig is off every time

With everything connected i measure 44.2 ohm on Pin 1-2

And yes, if i hold my finger longer than a second it burns really really bad

OK 44 ohms load on the 9vdc rail is OK. 9/44 = 200 ma. Assuming R38 is good then it looks like pass transistor is the cause of very hot heat sink.

50 ohm dummy load is typical max value I would use to bench test the AVR before re-install. I have an old ohmite 100 ohm wire wound rheostat that I place across the 9vdc and vary it from around 100 ohms to 50 ohms and monitor the 9vdc to make sure it will regulate and doesnt get hot.

Could just use your 50 ohm station dummy load which I assume you have and if you do not have one certainly need one to learn how to load and test the transmitter.

OK yes much neater install as the standard 4 hole panel mount SO-239 that I am familiar with wont lay flat in the hole. I had this image of a cocked connector!

For those of us with no milling machines or metal lathes a standard bulkhead connector is the answer.

Now if you have a friend with a machine shop you could be a hero to all of us if you had him fab a bunch of collars for the white nylon chain drive sprockets on the Drive Control shaft. A metal collar with two holes for the allen head set screws would be a slick fix. I am seeing more and more of these with really bad cracks and pretty easy to slip on the shaft and get the mesh/unmesh out of sync. Very important for them to be exactly in sync. Have to be tight tolerance for a collar to work (slight shrink fit). If you had to warm up to increase the ID and then slip on would be great. Just not so hot as to melt the nylon. I have even thought about installing small screw drive airplane hose clamp around them but the head of the set screw sticks up. I know of no glue that works with this gear material. I assume it is nylon but not sure.

Hello,
I have a problem with my TS820 on 40M, the transmit will turn off after a few seconds, I must restart the TS820 for emit again for a few seconds of course. When the problem occurs receipt work but the "drive" button no longer has any effect and others bands don't work also !
I precise that problem is only with 40M !
Have you ever encountered this problem or do you have any idea?

Thanks !
John

46940. Why oh WHY can't I get a break? TS520SE, fixed the DG5. 28,5 and 29.0 bands give 27. MHz.

Topic: 46940 Message: 46940

The poor thing has been CHICKEN-BANDED. Golden-screwed-up-drivered.

I tossed a long wire up on the roof tonight, for some sort of antenna, and worked on the DG-5 that came with this ill-fated 520SE.

It wasn't enough to get a loose screw to short the 900VDC section and eat the rectifier board. Mis-aligned, noisy receive couldn't be the worst of it. No, oh no. Not for me.

I got the DG-5 to work, powering it off a bench supply instead of the back of the radio. THAT is still a recipe for smoke and another set of diodes in the 14 VDC area. Not worth it, just power it off a bench supply. Stable as a rock, great. Finally getting to see the digital display, and it's working quite well. Half an hour's warm-up and it's stable like a table.

So I decide to 'exercise' all the bands. 160 was quiet, some Morse of course of course of course. No Mr. Ed though. Ditto 80 meters. 40 had some chit-chat, Florida and Ohio, heard from Utah (if he was at the home QTH anyway...) 20, kind of static-filled, and some more Morse down low, Maunder Minimums really stink and all that.

THEN I went to ten meters. the 28.0 selection on the band switch, 28.000 it it, and all seems well. Even heard some of the locals using it for a rag-chew. Toggled up to 28.5 notch, and ..... HUH?????

27.000.00

29.0 gives me

27.500.00

on the DG-5.

This thing has been up-ge-screwed to the children's band. And I have no idea which of the ham-handed, thumb-fisted, <expletive-deleted> - up methods were used to GET it there.

I sent a text/SMS message to the thief that sold this "works perfectly" radio to me to begin with. His "No Guarantee" on the bill of sale sure stopped me from getting anything back out of him. Plus he blames it on the previous owner before him, anyway. "He said ..." it was fine, and neither of them checked - if you believe either of them which I do NOT.

So, once again, I have been flim-flammed. Screwed, blued, and tattooed.

Is there a reference document anywhere that can be pointed to which will assist me in identifying and UN-<expletive-deleted>-ing-up this poor rig? I am in the unenviable position of having spent this much on it, so I might as well add in the rest and at least attempt to get it back to working order. I could just abandon ten meters altogether, and use it for the other bands, which are now working fairly well. (I think. It looks good so far anyway.) And I will do so, if I cannot get this thing repaired and in full working condition.

But that REALLY galls me. Being schnookered like this, that hurts, yes. But not being able to use two of the seven band selections chaps my butt. I'm going to take a run at it, whether I get it back to ten meter working or not. I'm sure going to try, and it would be of much help if there were documentation available to aid me in unscrewing the inscrutable here.

Which is the most likely modification that was used? I'm going to start with that, searching for the modifications available for doing this to a poor unsuspecting rig, until I find one that matches the conditions I find under the hood. I'll at least be needing to get REAL 10-meter crystals to replace the stupid-band ones, correct? Best source for those, please?

Advice, VERY MUCH welcome here. Thanks guys, in advance.

Sheesh, will SOMEBODY ELSE please take a turn in this barrel? I'm gettin' right sick of being in it.

While I agree it wasn't quite as described, it's not such a big deal compared to all the other things that were wrong with it - and I don't see that the other faults were necessarily down to the 27MHz conversion.

There seems to be an attitude among certain elements of the community that if an HF set has been modified for CB, then even if it's adjusted back it will never be "pure" somehow, and that it will have been permanently damaged. I'm not quite sure how this works, really, since you're just dropping the range of one band of the set 1MHz - as far as I can see, you need to swap a crystal and retune a couple of coils. No biggie, just swap 'em back and realign.

If you dig back through the mailing list (I know, the web interface is hideous) then others have trod this path before. It starts with checking what crystals are actually fitted, and seeing what replacements you need to get.

As an aside, the VFO on my TS520 goes far enough "below 0" to get the top three or four channels of the UK CB allocation - but obviously doesn't do FM ;-)

Wes,

It appears a previous owner has changed the 28.5 and 29.0 "HET OSC" crystals on the RF Unit's HET CRYSTAL board, X44-1160-00, to cover the 11 meter band. It's not difficult to change the 520 back to 10 meters, you just have to find the 2 crystals that were changed and replace them with the correct 28.5 and 29.0 Mhz HET OSC crystals.

Remove both top and bottom covers, turn the 520 upside down, front panel facing you, and the first small PC board, on 'your' left closest to the front panel is the HET OSC board. You will see some small square shaped component mounted on the front side of the board, those are the HET OSC crystals. Each band has one that is selected by the band switch.

The correct 28.5 and 29.0 Mhz band switch selected HET OSC crystals are

28.5 is 37.395Mhz
29.0 is 37.995Mhz

You can obtain replacement crystals, new, from International Crystals in Oklahoma City, OK or try Bob Mansker, he may have a complete HET OSC crystal board with all the correct crystals.

I think I know the answer to your problem. If it is the same arrangement as the TS820S, and I'm pretty sure that it is, you need a couple of crystals to replace those CB types.Once they are replaced it should just be a question of slight retuning of the synthesiser VCO as per the manual and possibly a quick tuneup on the RF side, but with a bit of luck the lazy $@#@@!@ who did the mods will not have touched those slugs and just relied on 27 MHz being VERY close to 28/29.5!
Best of luck!

Wes

Take a deep breath. Fortunately this is typically one of the easiest mods to reverse. Sometimes they install a toggle switch on rear panel and some wiring to the Het Osc board, but most times they simply change one or more of the 10 meter Het Osc crystals (usually X5 and X6).

For example very easy to look at X5 and see if it is factory 36.895mhz or if 35.695mhz. 35.695 - 8.830 = 27.865mhz. Just look at all the 10 meter Het Osc crystals to make sure they are as listed in your Service Manual. Any that are not need to be replaced back to design.

Factory crystals are available from International Crystal Company or you can get replacement board from Bob Mansker.

Hardest part is removing the Het Osc board to remove and replace the crystals. Sometimes they dont even bother to do any alignment changes, but I would do a complete coil pack alignment after getting the correct Het Osc crystals installed.

Also do a good visual of all the coils on all the hanging boards for cracked cores, coil formers twisted off their mounts, coil winding turns stretched and pulled off one end of the former. These guys are often shade tree mechanics.

What worries me more about any CB hacked KW hybrid (especially TS520 rigs) is what else they do in addition to just changing the crystals. There are other concerns and they have to do with QRO ing the rig and operator abuse. Some other visual things to look for (besides lag bolts to install mic clip!):

1. Plate choke in PA cage darkened brown or black. Can be over entire span of the windings or concentrated in the center.

2. Screen grid voltage to the Driver Tube and Finals has been increased.
A. 210 moved to 300
B. 470 SG resistor on Rect board super sized, removed, jumpered by wire, jumpered by 47 ohm resistor, or different value resistor installed.
C. Screen grid divider resistors for the Driver tube values changed or resistors overheated. R76 and R57.
D. Driver tube plate chokes discolored (not too common) L9 and L7.

I would measure the screen grid voltage at the Driver tube and 6146 final tube socket pins to make sure at spec in RX and TX modes.

Lastly I would make sure VFO tracks top to bottom to make sure they havent messed with alignment.

Clifford,

The TS-820 uses a "PLL" circuit to control it's frequency. The TS-520 (all models) does not use a PLL circuit but rather simple older HET OSC and VFO mixing at 2 different stages to control the transceiver's receive and transmit frequency.

While the TS-820 PLL circuit uses a "similar" mixing scheme, the PLL circuit in the TS-820 is quite a bit different than the older method of frequency controlling used in the TS-520 models.

The TS520 and 520S and 520SE are not PLL rigs. There is no VCO.??????????

Schematics and circuit descriptions are available at N6WK and other websites.

Gordon: The issue is that the illegal CB hack jobs don't stop with just the frequency conversion, but also usually include various attempts to increase the power output. Some of these power hacks can seriously shorten the rig's life, decrease transmit quality, and so on. It is difficult to find and fix all of the changes that may have been attempted, including botched attempts. .

I don't understand our FCC...I see ads on eBAY and other media for CB setups supporting 2KW and this has been going on for years, and while it may be impossible to go after all of the illegal users, vendors should be a lot easier.

While I agree it wasn't quite as described, it's not such a big deal compared to all the other things that were wrong with it - and I don't see that the other faults were necessarily down to the 27MHz conversion.

There seems to be an attitude among certain elements of the community that if an HF set has been modified for CB, then even if it's adjusted back it will never be "pure" somehow, and that it will have been permanently damaged. I'm not quite sure how this works, really, since you're just dropping the range of one band of the set 1MHz - as far as I can see, you need to swap a crystal and retune a couple of coils. No biggie, just swap 'em back and realign.

If you dig back through the mailing list (I know, the web interface is hideous) then others have trod this path before. It starts with checking what crystals are actually fitted, and seeing what replacements you need to get.

As an aside, the VFO on my TS520 goes far enough "below 0" to get the top three or four channels of the UK CB allocation - but obviously doesn't do FM ;-)

NOT TRUE.

The PA Tubes are not the only components being stressed. It appears you have not worked on very many hybrids or have not thought this out very well or perhaps not much tube transmitter and fundamental background? The PA works in concert with its Screen and Plate supply and they must be sized to address the rated DC input power and operating mode duty cycle.

QRO mods can result in:

1. Exceeding the Finals and Driver tube plate and screen grid dissipation.
2. Overheating SG voltage divider resistors and grid stoppers.
3. Burn up the Main and small RF Plate chokes.
4. Burn up the Rect boards

The objective of the QRO mods is to be able to routinely load these rigs to 300ma or greater plate current.

When you open a PA cage and find the Plate Choke burned black it is your first clue to look for QRO mods.
These morons even change the ALC RC time constants to reduce the delay time so that the ALC rail voltage comes back up quicker toward RF-1 between words and syllables so they increase the average to peak modulation. They use ALC as a form of compression. They could give a mouses rectum about splatter.

Gordon: All of these rigs are designed for a certain power and a certain duty cycle. When these are exceeded especially grossly you can loose the power transformer, the HV caps, etc in addition to the tubes. Excessive heat can cause damage to pc boards, etc. Over driving can cause splatter and other bad output...all in all, it's a mess to say the least, assuming that the mods were even made "correctly" and are reversible...

I have a few items for sale:

1. IRCI Kenwood Newsletters. These are the ones that Rob Pohorence N8RT published back in the heyday of the Kenwood Users Net. These are in a 2 inch 3-ring binder. I do not have a complete set. Earliest issue is #11 and oldest is #130. These contain more than KW Hybrid info. They cover rigs like the TS-930, TS-940 and others. Asking $30.00 shipped.

2. MC-50 microphone. Cord and strain reliefs all good. Keys are yellowed but lettering is good. I can provide a picture. Asking $55.00 shipped.

3. Polomar Engineers RX Noise Bridge w/manual (red die-cast case). Good for use with Spectro-gram or other audio spectrum analyzer software for adjusting the carrier oscillators for SSB frequency response. Asking $45.00 shipped.

4. Millen 90651 GDO with coil set. A little rough cosmetically, but works well. I can provide a picture. Asking $50.00 shipped.

Please contact me off the reflector. Can use Yahoo or AOL (wagstw46@aol.com).

Thanks
Terry K9TW

-----Original Message----- Well, any mods will inherently be reversible - it just depends how much effort you're willing to put in. I can't see how you could possibly get the thing hot enough to damage the PCBs, especially with that bloody great fan on the back. "Bad output" will go away when you drive the rig correctly, and it won't somehow damage the radio. Even doing fairly lengthy overs (think long low-speed MFSK overs) the TS520 doesn't even get warm. I can't imagine what you'd have to do to overheat it. Are you transmitting from a bakery? -- Gordonjcp MM0YEQ

46956. Nifty neutralization trick

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-13 00:15:45 UTC
From: Craig Roberts
Topic: 34493 Message: 46956

Hooray! My TS-830S is back in business with better than ever reception and full output on all bands.

Among the last tasks I performed was neutralization of the radio's new 8298 (6146B) finals. Seeking simplicity, I attempted the "remote receiver" method but, even with no antenna attached, the receiver's front end was swamped. Accordingly, its S-meter proved useless as a null indicator. I was about to put together an attenuator to help with the problem, but then ran across a really useful tip online. This requires an antenna switch, but most of us have one, so, here goes:

Connect the radio to be neutralized and the remote receiver to separate output (antenna) jacks of the switch and your dummy load to the "source" or common jack. Switch so the dummy load and transceiver to be serviced are connected. Follow the neutralization procedure as published. Enough of your transmitter's signal will bleed over through the switch to provide a usefully attenuated signal to the receiver. Using my old Heathkit HD-1234 antenna switch and TS-530S receiver, I was able to neutralize my 830's new finals very easily and quickly.

Two things.

1) Do you have the owner/operator manual? If not contact me off-list
and I will send you a PDF copy. In the manual it shows the power
requirements and consumption of the rig. 120/240 VAC 50/60 Hz. No DC.

2) Please add a signature block with at least your name and if you have
one your amateur call to the bottom of any posts to this list. We're
running this on old-fashioned netiquette, which requires identification.
(... Among other things like politeness, which is one of the things
some of the other members could use some work on, admittedly - as could
I and probably everyone else, at least now and again.)

I found the manual earlier this evening, and read through and noticed no mention of DC in it as well.

I was just wondering if it was an ability that was not specifically mentioned, or maybe if there was an easy conversion method people had possibly already done.

Best regards,
Don

OK. Thanks for the slap on the chops, I'll get a grip now.... Good to hear that the odds are somewhat less than I was afraid they might be.

Checked the crystals, they're a meg too low. I've gotten in contact with the idiots who shafted me with this thing and asked point-blank if they have the crystals still yet, banging about somewhere I fear, properly stored somewhere I hope. But I don't hope too much.

I will be going over the rig with an eye toward trying to find any other modifications. I already know the final cage is clear, nothing toasty in there, so perhaps there is not power modification, just the frequency.

Thanks again, all.

Not something Kenwood would tend to hide, I can assure you. Most of their manuals, bad type-setting, mistakes in the schematics, funky Asian-skewed grammar, and all, are pretty thorough.

Just to buy a largish inverter and use that to produce 120 VAC. Be sure it's a good sine-wave producing inverter, and not one with a crusty, badly-shaped square wave with lots of ringing and rough edges.

No, if you want DC operations that are built in, you need to get the S model, not the SP. (Same as with my 520SE. No DC power, among other things.)

Thanks, Joe. Yes, it certainly is a nice feeling to get on the air with a formerly unwell radio that you've restored to health. This one was especially gratifying since it arrived in very poor, disused and abused condition. It now looks and acts like new.

The repair/restoration would probably have been a three hour project for an experienced KW hybrid tech. It took me three WEEKS -- much of the time spent in nervous procrastination over the prospect of pulling and servicing boards with which I was unfamiliar for fear of "making bad matters worse." (I have some experience in this area as I have learned about other unfamiliar radios in the past). In the end, though, all is well. The credit goes largely to members of this forum who have offered advice, assistance, encouragement and, in one case, a rare and needed part! I hope in time to become expert enough to offer as well as request advice to fellow KW owners.

On another topic -- I heartily second Terry's call for an heroic someone to machine replacement collars for the KW hybrids' "chain drive". The original nylon ones on both of my radios (530S and 830S) are severely cracked at the set screws. As Terry noted, this is not atypical and can lead to sync problems with VC1, VC2 and VC3. I'm sure many of us would be willing to pay handsomely -- if not extravagantly -- for new sprocket collars.

46966. Nylon gear collar repair

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-13 17:27:13 UTC
From: Craig Roberts
Topic: 34493 Message: 46966

It's lunchtime here at the salt mine, so I've spent a few minutes researching adhesives that MIGHT facilitate repairing those inevitably cracked nylon "drive chain" gear collars that keep VC1, VC2 and VC3 in sync on our radios' Drive shaft.

Loctite offers an epoxy "plastic bond" product that allegedly works on nylon. So does 3M and a company called Reltek, whose website exhibits some highly technical white papers on the subject of bonding recalcitrant plastics.

Has anyone had any success with any of these products or similar ones? While I, like Terry, hope that someone will offer reproduction gear collars someday, I am not checking my email every three minutes to get the good news that it's happening.

One fella online illustrated a repair that appears to involve drilling minute holes on either side of the collar's crack, passing small gauge wire through the holes, then tightening the wires by twisting and securing with solder. I would prefer something a bit more elegant -- like bonding the nylon with some space-age miracle adhesive -- but am not prone to blind experimentation without some spare replacement parts at hand.

Any ideas?

Thanks and 73,

Craig

Perhaps a manufacturer of miniature (1/4" or 3/16" bore) sprocket and chain sets might have a useful product (subject to a little shimming or reaming out).

For instance:

http://precisionparts.wmberg.com/ecatalog/sprocketsPulleys/en/flt=19/SPROCKET

Just a thought.

Craig,

  Sometime in the recent past, a group member came up with an "elegant" repair..involving some copper pipe pieces. Take a look in the files section...or search the files section in "conversations." For the life of me, I can't remember his name or call...but it was a rather "elegant" repair.

Oh, yes. The solutions offered by Peter, KC2RBX, and the anonymous source of the copper tubing idea are terrific.

For me, the copper tubing sleeving method is the way to go. Thanks again, Joe, for the reference.

If Peter's QRZ.com photos are any indication, he is a dual KW hybrid and Drake fan. It appears that there are quite a few of us KW/Drake aficionados. In fact, several of the same personalities check into the weekend Drake Technical and Kenwood Hybrid nets. I can understand brand loyalties to the American manufacturers, but the mix of Kenwood hybrid (and maybe Yaesu?) fans among the loyalists is interesting.

I am among them. I used to work for Heathkit and have counted Collins, Ten Tec, Drake, Swan and even the esoteric Patcomm as among my favored radios as well. As I mentioned before, I had not owned any Japanese HF rigs until I acquired my first 530S last year and became a convert. Maybe that's more common than I would have thought.

Hmmm.

Hi,

Skip the inverter and look for a nice used APC SmartUps on ebay,
get one from a seller close to you to save on freight or even better,
get one without the battery and get a new battery locally inexpensive and
save on the shipping.

The SmartUps series is full sine wave, not step or modified and will
auto start without an y AC power with internal batteries charged.

Not as efficient as running the radio off the 120V AC but if you want DC then that is one
way.

Tom:

We are talking about the white nylon ladder chain 10 tooth sprockets on the Drive Control shaft for VC-1, VC-2, and VC-3 on the TS-530 and TS-830 rigs and not the white nylon flex grid member shaft couplers used on the band switch and the Plate load capacitor drive shafts.

The sprocket hubs develop cracks at the allen head screw tapped holes allowing the sprockets to slip and the air variable caps get out of sync which affects ability to peak the Rx and Tx and can make ALC drive indication very touchy.

Kens brass couplers no help here. Two completely different issues.

No problem your heart was in right place. Lots of folks want to jump in and help, but always best to go to the rig specific documentation and look at it first. Only takes a few seconds. Some pull the trigger without looking at the schematic or service manual. If a person doesnt own a TS-530/830 and has never seen the covers off kind of silly to be providing counsel.

It is one thing to make a mistake as we all do being human, but to offer advice when have no knowledge or experience helps no one. Always a challenge for new folks to sort out the BS from the good. Fortunately enough of us on here to keep each other straight. Just cant be too sensitive and think when corrected you are being dissed. Not saying you did that, but it is commonly done. We are social beast and some just feel compelled to join the fray. Maybe just need the recognition and group acceptance? With time you will earn the group respect by the quality of the counsel you provide.

Lots of no value KW hybrid advice on the various forums that I read. Some favorites:

1. I owned a TS520 30 years ago and here is how I remember it working or how I fixed it. I think the guy has slept since then and did he really ever have the covers off and would a brand new rig exhibit same operational problem as a 30 year old one? Pretty useless counsel.

2. I dont own a KW hybrid but my Yaesu FT-101 had same problem and this is how I fixed it. Even more Useless!

3. Why are you talking about ALC when loading the rig? Dont you mean Grid Current? What is the grid current reading? This person thinks we are loading an old Class C 6146 CW transmitter. No clue how RF drive level is peaked and indicated on a KW hybrid.

Many more examples but I see the above quite a bit.

As men we all know all there is about gas lawn more engine that wont start. Doe not matter what make or model we all jump in and share bits of wisdom. We know it from birth! Check the spark, does it have gas, is it flooded, did you choke it, did you prime it, has flywheel key shifted when the blade hit that rock and on and on. Now same 1/2 horse power electric motor wont start and there will be silence! Electricity and electronics shifts things to black magic!

So glad you got a TS520 and joined this group. Looked at your QRZ page and made me smile as it brought back memories of me and my Dad and my first crystal set!

Welcome to the group. Tom.

Love the Radiola! I'm also an antique broadcast set collector/restorer. The earliest one I have at present is a three dial 1924 Silvertone Neutrodyne (made by King). In the living room is another Sears Silvertone offering: an AM/SW console from 1938. It came with a bonus in mint condition: a brochure and world map, provided by Sears with the radio, promoting shortwave broadcast listening as a way of keeping up with world events. The map and statistical annotation depicts the military strength of major nations. At the time, the U.S. Army and Navy were dwarfed by the forces in Japan, Germany and even Italy (as we were soon to learn to our detriment).

Fascinating stuff! Oh - and thank you for passing along the legacy to your son.

46979. Sometimes forgotten cleaning step

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-14 17:23:07 UTC
From: Craig Roberts
Topic: 34493 Message: 46979

My recently completed TS-830S was left with one anomaly -- or at least what I suspected was one. The Drive, Plate and Load controls were all a bit "glitchy." That is -- to employ wholly non-technical language -- transitions were not smooth but jumpy in spots.

While this operational characteristic seemingly did not affect the radio's overall performance, it was annoying if not worrisome. It was also cured very simply by an elementary step that I should have taken at the outset of my repair and restoration work.

A cleaning of each variable capacitor's rotor wiper junction with denatured alcohol followed by a drop of CorrosionX (or DeoxIT, if you prefer) made the controls silky smooth both in feel and effect. I had been so concerned with decontaminating the notoriously troublesome band switch and the Molex connectors that I overlooked this simple and effective step in restoring the radio to like-new performance.

Now, I think I'll just enjoy USING the 830 for a spell.

OH - a couple of years ago Mark Gilger, WB0IQK, an old friend and mentor of many of us in the Kenwood and Drake communities, contributed a terrific tip on repairing the lately discussed nylon sprocket and chain drive assemblies on our hybrids. It's in our archives, but he's just worked up a new "tip sheet" on the method. It's simple, works well and involves NO disassembly of the radio other than removing the top cover. (Whoopee!) Basically, it involves applying a suitable adhesive to the cracks around the set screws, backing out the screws to relieve pressure on the sprocket wheels and closing the gap by cinching the sprocket with an encircling, small cable tie and letting the adhesive cure for a day.

As I mentioned yesterday, Loctite Epoxy Plastic Bonder allegedly works on Nylon. I'm picking up some at Home Depot tonight and will let you know how it worked with Mark's method in a couple of days.

Dont forget that the Plate Load air variable has four rotor shaft wipers.

Also, a "glitchy" Drive control is very often due to bad solder connections at the heavy square lugs of VC-1, VC-2, and VC-3 and not so much due to dirty rotor wiper contacts.

You can usually tell that by tapping on or tugging on each air variable. Of course have to remove the RF board to inspect these connections under good light and magnification. Same with the Driver tube socket lug soldering. These joints crack due to the pull and pressing of many tube change outs which flex the pc board.

On the 3 Drive control air variables I recommend removing the old solder and lightly filing the lugs bright and then re-soldering. Makes a world of difference with touchy Drive control. Receiver gain will often come up especially on higher bands and ALC indication will be stronger and not so jumpy.

Only problem I have with the Ty-rap method is you cannot get a good complete tight contact around the hub circumference due to the raised heads of the allen screws and cant adjust the sprockets with allen heads covered so have to make adjustments at the big sprockets. I suppose could try using a wider Ty-wrap and drilling holes for the allen heads?

Let us know what you come up with. I have rig here now with severely cracked sprockets. I am willing to bet that some hobby supply house has miniature ladder chain and sprockets made of brass or alum or SS with same pitch and teeth count.With all the robotics going on today just has to be replacements available from some source?

Yeah, I looked into the hobby supply idea. All I could find -- mainly for RC model use -- were sprocket wheels fitting 1/8" shafts with insufficient shoulders to drill out to .238". There are some miniature sprocket wheels made to fit 3/16" shafts, but it appears they would have to be shimmed.

It seems that some good hearted soul could make a mold from an stock piece and cast replicas in Delrin or whatever.

I'll keep everyone posted on the results of the WB0IQK sprocket repair experiment. I am also tempted by the copper tube sleeve method. It'd look cool if nothing else :-).

I have just emailed a plastic parts fabrication firm in Houston to see if having these sprocket wheels replicated in a relatively small quantity is feasible. This is one of those "how hard can it be?" situations but, as you point out, Terry, this may very well be too small a job for a commercial firm to bother with.

When I have some time, I will explore hobbyist blogs and forums to see if someone would like to tackle this job for fun.

I am trying to get a handle on the multiple emails about repairing and fixing the sprockets on the Kenwoods. I know for many there is no other way than to fix the broken sprockets with string, glue, tape, wire and tubing and maybe bubble gum. It almost drives me crazy to hear about these repairs but I know they are done because there seams to be no other way to repair them. So, let me ask some simple questions. How many would be consumed in a year or two if some replacement parts were made? Terry has offered to send me some sample parts to copy and I think I can make some nice replacements. I would be willing to make a few and have them reviewed by some experts, before and as I make them, that know the quality that is required. Then we can see if among us there is a need for some replacement sprockets. It seams to me if it is worth doing and if the radio holds some value then doing it right is important. I await some remarks.

It's possible that some of the sprockets here might work:

http://www.halebros.com/sprockets.html

I haven't compared the spec to the OEM Kenwod parts, but they look to be very close.

Gregory,

There is a market for everything, it's just how much time and effort are you willing to expend? Ken Kemski-k4eaa, spent uncounted hours of time & effort to reproduce the Kenwood KB-1 "weighted" spinner knob. It was a masterpiece! He had trouble with the anodizing to start..but when it was right...WOW! He sold out quickly..but due to some problems, he's a not had anymore reproduced. I am sure however that you can get many people "on the band wagon" with a re-manufactured sprocket. The operable design is sound...just the attachment method was not. I for one, would be on the "band wagon" with a well designed replacement part that could have some sort of a metal insert to have the set screws screw into

Hello Gregory,

I'm sure many if not most of us would warmly welcome someone who could replicate these sprocket wheels in a suitable, durable material. I do not know of the mechanical properties of Nylon, but supposedly the original Nylon wheels became brittle with age and may have shrunk in the heat to which they were subjected for decades. At any rate, all three of the sprocket wheels in my TS-830S and the same number in my TS-530S are cracked along the set screw holes from what appears to be unequal expansion of metal against plastic. I would guess that the vast majority of Kenwood hybrid owners have similarly damaged radios.

Heck, I'd buy at least a dozen of the reproduction items right off the bat to repair my existing radios and have spares for new acquisitions.

You wouldn't become a millionaire by serving this niche market, but you'd sure gain a lot of friends!

Kevin:

I would say if he is avoiding KW Hybrids he was probably the wrong fellow to begin with. Far better to send to someone who specializes in KW hybrids than a general radio repair shop or boat anchor repair shop.

I cant remember if we tried to help you or not? Are you certain you have exhausted the help from this group?

Nothing wrong with recognizing when it is time to send off to a "pro". Just make sure that you pack it to survive the rigors of the journey. Probably the highest jeopardy and the poorest attention to detail in my experience.

When I got my TS830s last year, the power switch on the rear was set to 240 VAC.It is still there. Main line voltages in my house are, however, 225 VAC, so one would assume that the switch should be set to 220VAC.

I use "Thunderbird" email software which has a "signature" option built in to the "account settings" under "tools".

Thunderbird has 2 signature options, 1) Create signature in the "account settings" by typing the signature in the text area then click the "check box". 2) create a signature file using a simple text editor such as "Notepad", save the text file to your hard drive (remember where you save it) then in the "Account settings", click the check box and enter the location of the signature file then click "OK".

Every message you send will use either of the 2 signatures so you don't have to remember to add a signature at the end of your message.

Each Thunderbird account you have can have it's own email/message signature.

Terry,
Yes I have gotten help here and sometimes it has been helpful, especially when I do something fairly ignorant. I do much better with my older Heath equipment because it suits my current skill level better and those rigs are not my primary radios.
I do think that it is time to send this one out. I really like this radio and it is the only one I have in my winter shack. I really want to get back on the air.
Best,
Kevin

Just curios if there is an illustration that shows what to touch to where in order to be safe in the HV areas? I think your supposed to ground a coil or something to the chassis using a insulated screwdriver, but I am not sure what to touch where. So I thought maybe a diagram might be out there.

I'm going to crack my beloved TS-530SP open and I want to learn how to be safe from the beginning. I have to replace the fan on the back of the finals box for one thing. Might do some cleaning and eventually replace some caps and resistors. But I thought I should learn the recommended way to do it safely first.

And a picture is worth a few words anyway.

Gregory,

I have located some of the said sprockets from a robotic manufacturer, they will not sell anything less that 1000 units, these are made of SS 316 grade, at $75.00 each I dont think I can afford to buy for my 5 radios. So if you do go ahead and are able to manufacture, then I'll take at least 5 sets for my own radios, then there will be the restorations that come in. Even if you were able to make the sleeves, this would be a huge advantage

Thanks for your input. This is a somewhat slow process, first
I'll get a sample of the original parts, then reverse engineer the part
with some changes to overcome the historical failures, then make some
prototype parts, review and test them by qualified folks, then evaluate
what it takes to make them in small quantity. I'll keep the group
posted as things progress.

This is not a service question nor a technical query. It's an alarming observation. (At least it's alarming to me).

I am looking for a nice TS-940S -- basically so I will have a 12V radio in the shack since I have sold everything except my boatanchors and KW hybrids. I began my shopping, as usual, on eBay. However, all I can find are purloined parts -- circuit boards, switches assemblies, pots, chassis bits, etc. But, no intact radios. This is the case for nearly all rigs "of a certain age", including our hybrids and those of Yaesu.

I know that y'all have noted the same trend. It disturbs me. Do the radio "chop shops" actually make significantly more money selling bits that they do peddling whole radios, even if they need some repair? I understand the needs for parts radios and I value our traditional sources for proprietary components. But, really....? Do ALL of our favored radios have to be torn asunder?

What do you think of this practice?

Craig,

I have an extra one that I just picked up. It's a 6 million s/n with
a few minor dings to the paint as most have. Email me direct for info.

Oh one thing. The TS-940s is not a 12 volt radio. You plug it into
110ac. So you sure your thinking the radio you want is a 940 and not
something like say a TS440s?

Mark

I tried to post this earlier, but apparently it failed. This link: https://sdp-si.com/eStore/Catalog may provide a replacement or substitute sprocket. They have lots of them in various configurations and the price seems to range from $6-$15 depending on style.

They have no minimum order, but under $50 will have shipping and handling added.

The customer service number is on the home page, and James at Ext 491 said he'd be glad to help find a replacement or substitute. They also do custom orders, but i didn't inquire as I didn't know the specs of the current sprocket.

This might be a source for sprockets that will work. Looks like they have a lot of possibilities, not sure if they have a direct replacement since I did not have specifications for the existing one.

https://sdp-si.com/eStore/Catalog

I called customer service and they said no minimum order, although under $50 they would add shipping and handling. The prices seemed to be in the $6-$15 range for a few I guessimated might work.

Customer service rep was James at ext 491 (number is on the website) and he said he would help you find the right one or a substitute. He mentioned that they can also fabricate a special order, but I didn't inquire as to the price lacking the specs.

Craig,

Your observations are keen "grasshopper!" I "surf" ebay all the time and know what your are talking about. So...say you have a 520, 820, 530, 830...that needs an RF board, IF board...or something else??.....what's it worth to you to get it back in working order? I do admit that my diagnostic skills are at time lacking...and ...I'm probably going to get some flack for this...it's easier to ...arrrrgggg....put in a "known working" board/part. The aforementioned practice was the prime motivating factor in me joining this group. My skills still have a long way to go..but I can now fix numerous problems...that prior...I could not. This skill was obtained by the generous help of several "tolerant" group members...and lots of home study.

  Anyway...IF your prime motivation is $$$...you can make more $$$ off just a few "prime" pieces...than a whole rig. There is/are several group members out there that sell parts as a business...so PLEASE don't take offense...you are not here/there to destroy these fine rigs to make a few $$, just helping to preserve them. I have purchased some parts off one particular ebay seller...he stated...he makes more $$ off selling parts...than selling a whole WORKING rig! XYL stated..one more rig and I'm gone....gee...I think I'll miss her! hihi

You see the same thing with musical equipment too. About a year ago, I offered to buy a non-running Ensoniq Mirage off a guy for ?50 (way over the odds, but it had a very clean case and a large library of disks) but he reckoned he'd get more if he parted it out.

I see he still has just about all of it up on eBay, from time to time. Oh well.

Well the reality is the rigs have not been made for many years and even discrete components on the boards are becoming more and more obsolete and often not available.

Sure it would be nice to keep every KW hybrid on the air, but the fact is we need people who make a business of selling boards, VFO, power transformers etc.

I have a complete set of spare boards for my TS-830s and quite a few boards for my TS-820 and TS-520. I rest easier knowing I have these in reserve. I even have some parts harvest boards that I use regularly. Real handy when you cannot buy an IC or a 10 meter Drive coil.

Having these boards and parts allows me to keep my hybrids in factory config and I am not resorting to soldering substitute Mosfets in different packages to the foil side of the boards (seen this more than a time or two with the Mixers) and a host of other mods that I would have to perform if I lived on a deserted island with no ready access to boards and parts.

One thing I do make a point of noticing on Ebay is the back panels of these parted out Hybrids and commonly I see they are 1 million series radios. That softens the blow quite a bit for me as I know people are not for the most part taking perfectly serviceable 6 and 7 million series radios and parting them out to make a buck.

It is kind of like going to the auto salvage yard and buying needed parts from a car that had over 200,000 miles on it. It met and exceeded its design and economic life and is now keeping others like it on the road.

I am sure glad we have a Bob Mansker. He has made it possible for me to keep several customer radios in service without resorting to making it a hybrid in the truest sense of the word.

Just my opinion.

Johnny:

I have looked at this site as well. Lets keep them in reserve and see how Gregory makes out reverse engineering the upper sprockets.

I didnt call this company as you did as I am not smart enough to give them the specs. I know that the bore is 6mm. I know that the ratio is 10 teeth to 16 teeth. I dont know the pitch. I am assuming all are metric dimensions and perhaps standard at that. I dont know how they spec the ladder chain.

Easiest thing for me to do would be to send them a gear set with chain and see if they can duplicate it. We can do that if Gregory determines he will not be able to economically manufacturer small number of these.

I dont know if they would be receptive to receiving the originals or not?

Appreciate your efforts and may still end up going back to this company.

The upper sprockets are very easy to change out and the ones that are more prone to cracking. The 16 tooth sprocket on the air variables with exception of VC-1 are not easy to change out. Requires RF board removal and unsoldering the capacitors.

Lets give Greg some time to see if he can produce the upper 10 tooth sprocket and if not then I can send gear set, chain, and drive shaft to your contact assuming he is willing to receipt for them and ship back to me.

One thing in back of my mind is how frugal (no cheap) most hams are. Perfect example is those still burnishing Aux and TR relay contacts instead of buying spare NOS relays while they are still available because they wont pop for $25 to $30. I have been down this road before when folks said they were interested and when part was found interest really wasnt there. More fun to use the rubber bands and bubble gum!

Thanks
Terry K9TW

The only issue with board swapping is board upgrades. I had and issue and changed out my IF board with known good board, radio worked perfectly. When through the suspect IF board and couldn't find anything wrong. Terry nearly went crazy after 3 weeks of assisting me, I'm just plain crazy. Anyway, ended up the new board had been upgraded and had a new 9V rail added. I purchased a new IF board complete with filters and checked against upgraded board and suspect board, new board also had new 9v rail.

My 2 cents worth from the hottest city on planet earth, according to UN.

Firstly, as I just explained to our friend Mark, I wrote my "What's happening?" post hurriedly when I should have been writing a news story about a really boring congressional hearing I had just covered. I was stalling.

At any rate, I AM looking for a 940 -- but not because it's a 12V radio. I was/am aware that it's a "mains" radio. I want a 940 because it's been recommended to me by a number of folks as a perfect "next step" in my KW acquisition journey. I'll get a little 440S or something along those lines as an emergency or portable rig to run off a 12V storage battery, should the need/desire arise.

As for the parting out of radios -- I certainly understand the arguments in both directions. I for one just fixed a number of problems on my 830 in an expeditious (and non-purist but military) manner by purchasing a "known good" AF board from an eBay vendor and installing it. So, on one hand, I am grateful that the radio breakers are in business and cheer them on. I just note with some concern the increasing scarcity of intact radios.

It's a mixed bag.

Hi,

I posted about SDP back in 2007 but did not have any issues with the sprockets in my radios way back then.

I did fix a few using 5 min. epoxy and some dental floss.

One coat of epoxy applied with a fine tip artist brush,
then a few turns of the flat unwaxed unflavored dental floss.

Once the epoxy has dried I applied a second coat and no problems.

Lets all take a deep breath and let this project get started and see if it will work or not. The or not is very possible. First with parts supplied by Terry I'll document all of the specifications that I can, short of the tensile strength of the nylon material. That will give us a starting data point. Second together with Terry and we will look at what causes them to fail and weather modifications to a replacement part are feasible, i.e. larger hubs, metal inserts, etc. THEN I'll make a few replacement prototype gear/wheel parts and we'll have a look at, and see if the tolerance, finish, strength, color and design make sense. I'll post the specifications when I have them, then share information about the success of the first few prototype parts. We'll keep you all posted. Let us get our feet on the ground and get a running start and hope we are successful. My initial guess is that if we are successful, cost will be VERY reasonable. For now lets just let the project progress. This is a hobby not a business venture for me.

Since the bad guys are making complete, functional and very deadly "plastic" semi-automatic weapons with 3-D printers (lots of pressures and stress on individual components) seems like copying a sprocket might be a piece of cake. Then it could be tested to determine if it would hold up in the KW application.

Kinda surprised it hasn't been mentioned until Michel's post.

Anyone have one of these critters? I'll check around the Sacramento area. Gotta be a "copy"service by now.

Greetings Group,

I need to clarify: I know Bob-ke5ftf, does a wonderful job...I did not mean to slam him or any other service or parts supplier. I have purchased parts from him on more than a few occasions...thanks Bob. I was making a direct comment about 1 seller on ebay who does take early & late serial numbered 820, 530 & 830's down for parts...also dismantles 430 & 440.

Again...apologies

Gregory:

Industrial Engineering Bachelor's degree. I can likely help a bit here.

Strength of nylon is a known, I can give you those figures if you really want them, but just about ANY metal better than pewter or pot-metal is going to be stronger than what is in there. Nylon is great stuff when it's the right stuff, but this was an economical decision, not an engineering one, I'm sure.

Even pot-metal is likely to be stronger, frankly. These radios were just not intended to last as long as they have. They used nylon for ease of manufacture, and cost, originally.

"What metal are you most comfortable fabbing?" will be the type of material to use, be it brass, bronze, or 17-7PH Condition A aero stainless steel. Titanium, anyone? (Nice for what it's good for, but a stone BUGGER to machine.)

Forget the 17-7PH, Rockwell 301 would be a hundred-fold overkill in this application. I am of course being facetious, for the humour-impaired on the list, about using aircraft-grade stainless here.

As for finish, a flat 120-150 silicon carbide grit polish would be a bit better than required. These are internal parts, and not seen. Any finish which is not so rough as to wear the chain will suffice. Medium 120-150 grit will be great.

Colour? Who Gives A Rat's Rump???? The base, untreated colour of the material you decide to use will be perfectly acceptable, whatever that is; from goldish to stainless-silver-grey, it will be just dandy.

The design can be a very-near exact duplicate of the original part. I suspect that a slightly-longer center hub, with a little thicker wall, to accommodate the hex-head set screw, would be the only real change that would make much difference.

Make it somewhat thicker where the set screw is located, so as to give it a little more material for the threads to grab; maybe one, possibly two more threads depth than the nylon ones, would be really good. Helps keep the set screw from stripping out and ruining an otherwise good sprocket. (Heavy hands on the old allen wrench are not unknown....)

Terry, Mike, Gordon, Et Alii, please comment here, that IS where the nylon originals are cracking and failing, is it not? If a touch thicker hub in the center where the set-screw is located would help with both rigidity and longevity, or whether the current thickness is sufficient, I am not competent to judge. The "thicker hub" recommendation is off the cuff, from similar problems in conveyor belts in my past, so the advice of the other more experienced list members is needed here, they should chime in about this bit.

I tend to go along with the decisions of the original engineers where they are not likely to have been over-ruled by bean-counting. The use of a plastic sprocket instead of a metal one is an example of something I was taught to be a red-flag indication of accounting getting one over on engineering. Wear parts with a tight tolerance, being made of a plastic, is a textbook example of what happens when they save too many pennies. It's penny-wise but pound-foolish, when you wind up with a design so otherwise-good that it outlasts its design obsolescence projection by a factor of at least two time.

The simple change to a more-rigid, longer-wearing material, with NO other changes in the design of the part is very likely going to provide a sprocket that will last fifty or more years. Possibly closer to 100, since the application is low-speed, low-impact, and not terribly stressful on the individual parts.

Sheer abrasion from the motion of the chain will be the only real deterioration factor here. So it's truly going to be your choice of your favourite metal, a mild polish, and soaking up the adulation of your peers.

Lots of the latter, I should think. This has been needing an answer for a long time now, from the look of the interest the posting has generated.

So, does this answer any of the questions about finish / colour / design?? If you have any other things that you think I might help with or need help, please feel free to contact me off the list, I'd be more than glad to lend a hand. The calculator's all warmed up, and it beats the heck outta my old deci-deci-log 18-inch slipstick anyway. (No guessing where the decimal point goes!!)

And by the way, I envy you the production facility. I'm not even in possession of a Unimat any longer. Have fun storming the castle, OM, and enjoy the sound of the milling machine in production mode. It's a favourite noise of mine, when there is a smooth CNC program running and you know you've cut the therbligs down to near-zero.....

> and stress on individual components) seems like copying a sprocket might
> be a piece of cake. Then it could be tested to determine if it would

The plastic resin used in 3-D printing is not exactly known for its lasting power. It tends to become brittle and sort of fall apart over time. The volatiles out-gas, and that means the plastic fails within a year or two, more often than not.

(As for making firearms with these printers, I would not pull the trigger on one, the likelihood of eating the receiver as it comes apart in my hand would be much too great. The first shot, maybe you get away with it. Second and subsequent? Not on your tin-type. Not even on your Daguerro-type.

The resins used in laser-cured 3-D printing just aren't THAT strong. It's fantastic for one-off prototyping, and within the constraints of the material and methods used to create things the 3-D printing technology is one of the more fantastic things technology has done for us in recent years. But it isn't perfect, and it really just isn't meant for long-term use parts. That's not a slam on the technology, just an admission of reality and the limits of plastic resins.)

Joe

I didnt take it as a slam on Bob. I dont know if Bob cannabilizes late serial number working rigs or not. I hope not but no way for me to know.

I was just trying to point out the other side of the coin. Without original spare parts there would be a lot of hybrids that would not be repaired or repaired in non-standard configurations.

I hate to see them being parted out, but understand it is necessary evil.

Same thing when people easily give up and sell Hybrid rig for below market price when all it took was simple repair. Hate to see them do that but same as with a car that is nickel/dime-ing you to death. At some point you just sell or trade and get a different model.

Terry K9TW

Hey gang as Gregory has requested lets give him a chance here.

At minimum we may end up with a good set of dimensional specs that we do not presently have so that someone might be able to fab new sprockets from metal or some other durable material and as Wes mentions maybe re-design to address root cause of the cracking.

I dont know why they fail. Just looking at them it seems that there is not enough "meat" left on the sides of the hubs after tapping the holes. I have read some theories that say there is entrained moisture in the nylon (and I am guessing it is nylon?) and that it dries out over time in a high heat environment and cracks are induced. I simply do not know.

At this point Gregory knows that there are couple of you with education and machining backgrounds willing to help. Let him decide when or if he wants to avail himself of your help.

Also nothing stopping anyone from a parallel initiative of re-design, machining or finding a supplier. I have given complete sample set to Gregory. When he is finished with these originals he will return to me and I can make them available to others.

I only have one complete set. If someone else has them available and wants to offer up for analysis and measurements etc feel free to do so.

So for now you can proceed with parallel initiatives or stay tuned for progress reports when there is something to report.

Here is fellow who is fabing nylon collars to press over the sprocket hub and secure in place with super glue. People have used safety wire and wrapped and twisted, nylon Ty-wrap cable ties cinched up, dental floss wrapped coated with adhesive, copper tubing sleeves, machined collars and a host of methods to "fix" the problem. Fix means prevent slippage on the drive shaft.

Our sprockets do not have the brass knurled inserts. Ours are all nylon but gives you an idea of what a sprocket looks like. The crack doesnt show well. It runs across the tapped hole and all the way to the bore of the hub. Sometimes hair line and sometimes spread wide open. There are two tapped holes 120 degrees apart. OD of hub is approx 15 mm and the bore is approx 6 mm. Now you know everything I know about these sprockets.

http://www.kx4om.com/Files/Tempo2020SprocketRepair.pdf

If you want to see more about this Google on Tempo 2020 sprocket repair.

So far, the discussion about replication of the nylon sprocket wheels in question has centered around machining.

According to Dupont's literature, "Delrin? acetal homopolymer combines lubricity and wear resistance with the stiffness and strength needed in parts designed to replace metal."

I have used Delrin? rod as element spacers in my aluminum Moxon antenna designs without any apparent deterioration despite exposure to the outside elements for about a decade now.

Could not a mold be made from an original upper spocket wheel and replicas of Delrin (or other suitable thermoplastic) then be fashioned by injection? I would think - though I admit to total ignorance of mechanical engineering -- that this method would be easier and less costly than machining. I'm guessing the OEM Nylon pieces were made by injection molding.

http://www.dupont.com/products-and-services/plastics-polymers-resins/thermoplastics/uses-and-applications/mechanical-gears.html

Oh - I hereby retract all negative comments about the practice of parting out our radios. The arguments in favor of making spare and replacement circuit boards and other components available to renew our radios are persuasive. I stand -- or rather, sit -- corrected, y'all.

I am the one using the term "machining". I did not mean there are not other processes. Perhaps I should have said fabricate?

I mean it in a generic sense and not a precise technical process. I am not conversant with the best manufacturing process. So disregard when I say machining a new part. I am an electrical and electronic guy and only been exposed to mechanical world thru many years in electric power production.

Same as if I said it should be "welded". That would be my generic term for SMAW, or TIG, or MIG, or Centrifugal, or Brazed or Heliarc or ??? Just as I am not a machinist or mill wright or machine builder I am not a welder.

I dont care if they are Injection Molded, CNC machined, Casting, 3D printer, flame cut, forged, laser cut, or what the manufacturing process is.

Gregory's first goal is to precisely replicate the dimensional attributes and then he will look at improving upon the design by selecting better material properties and sizing. I dont know if he will end up with Delrin, ABS, Nylon 6-6, Fiberglass, Urethane/Epoxy Resin or what kind of "plastic" (again generic term plastic as opposed to metal). Frankly I dont really care.

Sorry for confusion. Only machining I have pursued in the past was the fabrication of press on metal collars. A lathe and drill press was involved.

No more mention of "machining" from me.

Terry K9TW

47043. 530 9V reg problem

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-16 18:36:02 UTC
From: Jan Servaites
Topic: 47043 Message: 47043

I have 9V regulator problem in my TS530.
I'm getting:
2.7V at TP6 (test point to measure the 9V);
18.6V at the 14V wire
12.2V at the "12" pin
And on the rectifier board, I get 15.8VAC at the 14AC wires.
What typically goes bad on the 9V regulator circuit?
Thanks,
Jan N8CBX

Terry,
Sorry I did not respond sooner, I was working the last couple nights, 12 hour shifts. But I did want to thank you for your kind and thoughtful reply and let you know I was not at all feeling dissed, quite the contrary. I joined the group mainly to learn since this is my first hybrid and I am still on a steep learning curve. I have no problem with being wrong about something and being corrected. I had happened to be on Ken's website buying the dummy load kit and saw the brass retainers and then without going back to his site and seeing the thread responded off the cuff, a little too fast, before I completely understood the conversation or what it was I saw on Ken's website.

Craig, your radios sound great, that is really something getting the original brochure in such nice condition. Very interesting about the military forces of other nations at that time and on the brochure printed in the US actually showing that! Also amazing to think how the US came together under those circumstances and put up such a national effort to win the war at that time in light of it.

The story of my Radiola 20 is I saw a youtube video by "AllAmericanFiveRadio" on that radio a few years back, and I loved it, so I did a little research and decided I really wanted one, and use it to learn about radio restoration. I was fortunate to find one on eBay that was right near me in Albany NY (I am 22 miles south east of Albany) and came from a collector here and was well taken care of. The neat thing about it is it still has the pencil marked station indicators on the dial, and someone wrote "WGY" on it which is here in Schenectady NY and was one of the first big AM station in the country since 1922, so the radio was always local to this area, and will stay here. I have only repaired a stuck rheostat and hunted down a missing escutcheon so far, I still need to replace the couple old caps in it and build a battery eliminator for it. I have first been working on a couple cheaper AA5 radios to learn more before I work more on the Radiola because I really want to gain more experience and do a good job on it. Anyway, that is also the mindset that lead me to put together a TS-520 station. I love the older radios, and Kenwoods especially, and figure this is something I can learn to work on myself too.

I'm finally getting back to working on the radio.
I now have resistor on a wire to discharge the stored power in the radio.
Now I have a new problem.
I replaced the two 56k resistors one had infinite resistance.
Now after replacing them all that happens when I turn the radio on is the fan and meter lights com on.
Is their any thing that would be obvious to look for?
Thanks
Dale (KD0GES)

For years, my local Police Department dealt with broken gear teeth on the rotating lights inside their "Code 3" brand lightbars. They came up with a different type of plastic (dark gray/black) that remains intact, even with years of use and heavy UV exposure. They might be able to provide some background on the material used in later issues of the MX7000 lightbar. If that plastic is available for machining the sprockets on the KWs...it could prove to be a long-term winner. If those trying to re-invent the wheel here wants to give Code3PSE a call, their number is (314) 426-2700 in St Louis MO. Online at http://www.code3pse.com/Code3/contact_us

Hi Jan:

What the heck does this have to do with 1500watt tetrode amps??

One thing to remember is that the "voltages" noted on the Rect Board transformer secondary windings are not voltages, but labels or designators for the particular dc supply. Having 18.6vdc at 14A on the AF board is normal. You are looking at the output of a full wave bridge rectifier with capacitor filter. The secondary winding labeled 14 is not 14 VAC. It is closer to 15.5vac to 16.0vac as you have measured.

800 is not 800vac secondary voltage. It is approx 340 to 345 vac as the nominal "800 vdc anode supply" is a voltage doubler. These transformer secondary schematic labels cause a lot of confusion.

Of course 12.2 at output of the first linear series pass regulator at TP-6 is good. That 12vdc is then the supply for the 2nd linear series pass regulator.

With 2.7vdc at TP-6 I would first try cleaning and adjusting Voltage Sampler trim pot VR-2. If that doesnt help then measure the voltage at the cathode of Reference Zener D14. Should be 5.1vdc to 6.1vdc.

Terry,
What does it have to do with 1500 Watt tetrode amps.....? Absolutely nothing (LOL), but I digress.
I pulled the board out of the 530 and have it on the bench. I'm powering up the "AF" board (X49-1150-00) at 14A/G14 with about 19.8VDC and checking the following:
12.3V regulator (at "12");
9V reg (TP6);
3.2V reg (pin5, plug10), using my meter ground at the aluminum heatsink (GND for regulator tests).
I'm not getting any regulation at all. So, I'm looking at the shunt regulator (PNP) transistors (2SA473).
I crossed the 2SA473 to a NTE152/153, so I might replace them and retest.
Do this sound okay so far, Terry?

I had a typo. You dont want 12.6vdc at TP-6. You want 12 vdc output at 12vdc terminal post. You want 9vdc at TP-6.

Jan:

19,8vdc input is a little high and I know it shows that on the schematic, but you dont need that much. 18vdc is plenty.

What load are you using to see if it is regulating?

Need to place dummy load resistors on TP-6 to ground and monitor the 9vdc to see if it holds with varying load current. I would place 50 ohm resistor and then a 100 ohm resistor and see what the 9vdc does with each load.

9/50 = 180 ma of load and 9/100 = 90ma load. Dont leave 50 ohms on too long.

Perhaps you had loose board mounting screws and poor ground?

Terry,
Load- I'm just using the AF circuits on the board as a load. It seems
the 12V regulator isn't working at all, so I'm trouble shooting it
Shunt transistors - I pulled them both and they tested ok w/multi-meter.
Zener D15 - Pulled and tested ok; Its a 0.7v zener?
Going to pull the signal transistors in that 12v reg circuit and test
them next.

Terry,
Could a 7812 linear regulator replace the whole 12v shunt regulator
circuit? That would be great if possible.
If so, then replace the 9V circuit too with a 7809?
I remember someone said they have done that. I'll check my emails.

Yes certainly can replace both regulated supplies with 3 terminal devices if you dont care about returning rig to original config. There is nothing wrong with this very mature regulator design. Of course your rig and free to modify as you see fit. I am confused about your trouble shooting efforts.

I would not just use the load on the AF board to test the 9vdc or 12vdc regulated outputs. Need a varying load and monitor the regulated voltage as you vary the load on each bus.

I dont understand why you say the 12 vdc isnt regulating. What are you doing to see that the voltage is varying under load? Are you saying with 18vdc applied to Emitter of Q26 the 12vdc is varying as it sits there. .Did you scope it and look at ripple? Should be none.

No reason to pull zeners and series pass devices until have determined thru troubleshooting that they are defective.

Terry/Jan,

The very early serial numbers of the 530s has known issues with tracks cracking and lifting foils tracks, especially on the 9V rail, more so than normal. Must have been a bad batch run, as this was an issue straight out of the factory.

Were the input voltages to the AF board correct?

Have a close look at the foil side of connector 8 and 9, these 2 connectors have created many issues in the past. Need to use good lighting and magnification.

Should be able to find that defect via classic troubleshooting before removing boards and pulling components.

All you need is a voltmeter and variable loads. Hardest part is access to some of the EBC leads if it goes that far.

Several years ago I repaired my sprocket in
several of my hybrids using the following posted procedure.

With all the talk lately about this subject I
figured it was time to check and see how my
repairs were holding up. I removed both radio's
from service and removed the covers and found all
were as I left them several years back. The
repair was super cheap and simple, and seem to be holding up well.

"Yes certainly can replace both regulated supplies with 3 terminal devices if you dont care about returning rig to original config..."
Terry,
If I can replace about 27 discrete components with just 2ea 78xx regulators and about 4 bypass caps, I would think that's an intelligent engineering decision. With a 30 year old radio, I not concerned about the insides, I want the radio to work well so I can use it.

Dave,
The PCB traces look excellent, no cracks. The input voltages (14A/G14) are good. The 12V is pulled down to about 4-5V for some reason and that affects all the other (9V & 3.2V) voltages. A single point failure design. The 820 is not like this, and I never had any regulator problems with the 820, other than the dirty/oxidized 9V reg. pot.

And no doubt improve the performance too! Lovely stable power supplies, which will help things no end.

I have old radios, I have old synthesizers and I have old cars. I like to keep things as original as I can, at least as far as the character of the machine is concerned. If a repair involves upgrading something to a modern component that will improve other aspects, then yay, great. I'm not about to spend months tracking down 1970s asbestos brake pads for the Citro?n when I can buy nice modern composite ones for pennies in any high-street auto parts shop.

Your radio and free to modify anyway you chose. It is the essence of the hobby for some folks. Done my share of mods over the years.

Since I repair these radios for paying customers I often have to spend my time in discovery and removing ill conceived and poorly executed mods.

Because I do perform repair and alignment for paying customers I had to learn how the circuits work and how to troubleshoot to the component level. That is the kind of help I try to dispense on this forum. It is my idea of fun. Helps stave off old timers disease and forces me to keep learning.

If these KW hybrid radios are used for the designed modes of operation they can still hold there own quite well today. Especially true of the TS-830.

As long as parts are still available I intend to keep my two TS-830 full filtered daily drivers as designed and built. Just my approach to life.

Lots of other mods you can undertake:
1. Replace the old fashioned ring diode balanced modulator and product detector with MC1496.
2. Replace that 1st Rx Mixer with a NE602 or 74HC4066
3. Replace that 12BY7A Driver stage with a couple of toroid transformers and a 2SC1971 or similar.
4. Replace that obsolete Ant relay with Pin Diode electronic TR switching.
5. Add a mosfet shunt regulator to the finals screen grid supply.

Just a few for starters.

When you came and asked for help I had no idea "replace with 3 terminal regulator" was an acceptable response.

I think people are confused about why we have Linear Series Pass regulator supplies (Not Shunt Regulators). Yes a regulated supply can address variations in the input supply voltage, but that is not primary reason why we have regulated 12vdc and 9vdc power supplies. We have two very different load conditions presented by a transceiver.

To say you are using the load on the AF board to test the regulator misses the point. Those power supplies see two differing loads in operation. You are more concerned about testing if they can hold voltage constant under varying load than you are variations in the input voltage (AC mains). There is a load current in RX ,mode and a different load current in TX mode. If you are testing the power supply with a fixed load you have no idea if it can regulate.

This is why I suggested using two values of dummy load resistors.

I think best if you do install 3 terminal regulators.

Dave:

No reason to be sorry. You may in fact be correct board may have been pulled prior to troubleshooting or to provide access to foil side for easier EBC voltage measurements. Some folks get impatient and are very quick to start pulling components.

I have a SMT test probe lead for my DMM that has a very thin needle point. I also commonly use corsage or floral arrangement pins that can get at craft/hobby stores. These can be had in 2 to 3 inch lengths. I slip insulation over all but small gap at top and at the pin point. I connect via mini-grabber test lead to top of the pin to what ever test meter I am using. I like these as they have either a tear drop or pearl drop plastic ball at the top for grasping. Often can just stick these in the same top side hole as the EBC lead and they will stay there while you take the reading.

Jan is comparing apples and oranges somewhat with his TS820. The 820 has no regulated 12vdc supply and if its 9vdc regulator on the AF-AVR board goes bad it will greatly affect his 3.2 vdc RF-1 voltage just as it does on the 530/830 regulated supplies. The TS820 uses a trick to allow them to use a cheaper and lower dissipation pass device and that is a 68 ohm shunt bypass resistor around the pass transistor. This was common circuit in the old console TV power supplies. The TS820 AVR board is not immune from losing reference zener or series pass transistor. Replaced a few over the years.

It appears he measured D15 zener using the diode test function of his DMM. It is not a 0.7vdc zener. He is looking at barrier voltage. It is a 9vdc zener. In circuit should measure close to 3.2vdc at base of Q23 and approx 9vdc across R77 zener bias current resistor.

Dave it appears he is moving on to LM-317 or similar modification. His choice, but kind of sad as appears he asked for help and didnt let the ink dry before he started pulling components. Not something one would do unless troubleshooting indicates the need or you have exhausted troubleshooting.

One other thing you can help him with in the event his 3 terminal mod doesnt work out for him. I would measure the resistance to chassis ground of the 12vdc output and the 9vdc output. I dont have good notes but based on TS-830 I would expect something on order of approx 40 to 50 ohms for 12vdc and 80 to 100 ohms for the 9vdc load. If significantly lower resistance could indicate a fault on either bus and account for low output voltage. I typically test all these AVRs by loading with a 50 ohm dummy load resistor. Shouldnt see much more than approx 10 mv voltage drop.

Always need to determine if it is regulator fault or a load problem.

I frankly have never heard of the foil trace problems on the TS-530 that you mentioned.

With your 530 experience I need to move on and try to help others.

Well friends, today I had time to do the alignment of the coil package, as suggested. Although I followed instructions, it didn't change the 28,000- 28,500 and the 28,500- 29,100 Mhz low output, when tuning VFO above around 200..... both the band segments react the same way....
When only receiving, it works perfect.
What puzzles me though, is that if I try to tune say fx 28,500 on the first band segment, next to nothing, but, if I change band segment, I have full output, after tuning..... on same frequens....
What is wrong with this rig?

Lars:

1. Are you saying that below 200 on the VFO dial that your 10 meters output power is good (80 to 90 watts output into dummy load at 200ma Ip) and above 200 on the VFO the output falls off?

2. Are you saying this only happens on these two bandswitch positions and all others bands are normal?

3. Do you have an RF probe and VTVM?

4. Did you adjust the Het Osc coils by measuring RF voltage at TP-3 on the RF board or just by ear?

From: <famtech@...>
Topic: 47068 Message: 47068

My TS-820 works fine on USB/LSB but not on "CW" or "TUNE". Say on 40-meters and when placed in transmit, there is no output when the carrier control is advanced and the display reverts to 9000.0 instead of the correct frequency. Receive works fine in all modes. YG-88C is installed and the connector at IF-2 is in the correct position. The relays are fine and their function are OK. Any thoughts ??

Topic: 47069 Message: 47069

Hello-I am going through a TS-820S and I have never had to adjust the trimmers in the carrier unit in the few I have aligned, but on this one I feel I need to. This radio has the CW filter and when I tune to get a beat note the signal is just about out of filter passband. LSB and USB operation appear OK to me based on the overall tone and sound. When I receive a carrier in either LSB or USB, and tune it for maximum S-Meter reading, I get a beat note of around 700-800 cycles. When I switch to CW from either of these modes, there is only a slightly discernible beat note, with much less signal strength. If I tune the carrier for maximum strength in CW mode (nearly as high a reading as in LSB or USB)there is a very low pitched beat note that is barely discernible. If I tune for a normal beat note the signal strength is extremely low, just about out of filter passband. I have tried to make sense of the alignment instructions for the Carrier Unit but I am lost on what to do there. Thanks for any help, Byron WA5THJ

47070. TS-820, No transmit on CW or TUNE ..

My TS-820 works fine on USB/LSB but not on "CW" or "TUNE". Say while 40-meters and when placed in transmit and "Tune" or "CW", there is no output when the carrier control is advanced and the display reverts to 9000.0 instead of showing the correct frequency. Receive works fine in all modes with the display showing the frequency. The YC-88C CW filter is installed and the connector to IF-2 is in the correct position. The relays are fine and their function are OK. On the 10-meter bands receive, the display's readout shows 25 Mhz and jumps around. Measured voltages seem correct. Any thoughts ??

Please someone correct me if I'm wrong, but the "9.00" (or 19,000 or 29.000 on other bands) symptom says that the CARRIER signal to the PLL is not there, does it not? Bet FSK is out, too.

If there is no CARRIER TWO there will be no CW or FSK transmission. CARRIER ONE does CW and FSK reception, and USB/LSB TX and RX both.

So making sure the Carrier One and Carrier Two boards have the proper voltages as shown on the Service Manual charts, pages 42 and 43 in the paper book, pages 45 and 46 of the PDF file I have here, show the required voltages at the test points on the carrier outputs to the ring modulator and the PLL circuits. I'd start there.

Now.please, someone tell him where to REALLY look, since this is my guess and I don't even have an 820, and tell me where I'm full of stinky brown stuff and need to go back to look at some obvious thing I missed. This is my guess, and where (absent any better advice) I would start looking for a fault, in the carrier oscillators.

Jim, wait for the advice from someone who knows what he's doing. This is for me to embarrass myself and learn something. Sorry to get in the way of fixing your rig.

(Thought Jim, you might look at the troubleshooting chart in the service manual, though. It lists that 9.0000 MHz reading on CW in one of the symptoms, straight up. I went from there to the functional descriptions and the block diagrams of the circuits, and traced what signals were needed, and where they would be --different-- for sideband versus CW. The carrier boards popped right up.)

If you don't HAVE the service manual, I highly recommend spending the time and bandwidth for the download. I got them tonight after seeing

your post and thinking it would be a good thing to work on troubleshooting skills, and so went to the N6WK.com/kenwood/ download site and got them there. (There are other places as well, find one you like if that one doesn't suit your tastes.)

Good luck, OM. And please somebody give Jim some GOOD advice and help now that I've stuck in my oar?

Terry,

The foil trace problem was in the very early generation AF boards. Somewhere in the vicinity of around 200 boards (production issue??), have seen a couple here over the years, its almost as if the foils fell off after a few hours use. Some of the problems I have rectified is due to poor soldering techniques of jumper wires done by some who have attempted repairs.

Will be a shame if the board is modified, but that is the owners choice. I can see new faults being introduced, albeit that I haven't put too much thought into the modification. Will do some measurements later just for the note book

Hope your snow is melting and your not getting flooded. Our heat wave has passed for the mean time, but still have bushfires going.

Subject: RE: [TS-520_820_530_830] RE: 530 9V reg problem

Dave:

No reason to be sorry. You may in fact be correct board may have been pulled prior to troubleshooting or to provide access to foil side for easier EBC voltage measurements. Some folks get impatient and are very quick to start pulling components.

I have a SMT test probe lead for my DMM that has a very thin needle point. I also commonly use corsage or floral arrangement pins that can get at craft/hobby stores. These can be had in 2 to 3 inch lengths. I slip insulation over all but small gap at top and at the pin point. I connect via mini-grabber test lead to top of the pin to what ever test meter I am using. I like these as they have either a tear drop or pearl drop plastic ball at the top for grasping. Often can just stick these in the same top side hole as the EBC lead and they will stay there while you take the reading.

Jan is comparing apples and oranges somewhat with his TS820. The 820 has no regulated 12vdc supply and if its 9vdc regulator on the AF-AVR board goes bad it will greatly affect his 3.2 vdc RF-1 voltage just as it does on the 530/830 regulated supplies. The TS820 uses a trick to allow them to use a cheaper and lower dissipation pass device and that is a 68 ohm shunt bypass resistor around the pass transistor. This was common circuit in the old console TV power supplies. The TS820 AVR board is not immune from losing reference zener or series pass transistor. Replaced a few over the years.

It appears he measured D15 zener using the diode test function of his DMM. It is not a 0.7vdc zener. He is looking at barrier voltage. It is a 9vdc zener. In circuit should measure close to 3.2vdc at base of Q23 and approx 9vdc across R77 zener bias current resistor.

Dave it appears he is moving on to LM-317 or similar modification. His choice, but kind of sad as appears he asked for help and didnt let the ink dry before he started pulling components. Not something one would do unless troubleshooting indicates the need or you have exhausted troubleshooting.

One other thing you can help him with in the event his 3 terminal mod doesnt work out for him. I would measure the resistance to chassis ground of the 12vdc output and the 9vdc output. I dont have good notes but based on TS-830 I would expect something on order of approx 40 to 50 ohms for 12vdc and 80 to 100 ohms for the 9vdc load. If significantly lower resistance could indicate a fault on either bus and account for low output voltage. I typically test all these AVRs by loading with a 50 ohm dummy load resistor. Shouldnt see much more than approx 10 mv voltage drop.

Always need to determine if it is regulator fault or a load problem.

I frankly have never heard of the foil trace problems on the TS-530 that you mentioned.

With your 530 experience I need to move on and try to help others.

Byron:

You state that you have Never had to adjust TC1 and TC2 when aligning a TS820. I hope you dont mean that you skip that step of the alignment procedure. I would always measure it and then adjust based on the as found measurements.

I have never had any KW hybrid on bench that I did not as matter of routine adjust the " Carrier Set Point" or the "SSB Frequency Response". It is of course to large measure a "user preference adjustment" with some preferring a more bass response and others wanting a more "communications style" audio. Just have to remember how you set in in Rx is how you will sound in Tx.

First thing you have to realize is the Service manual has lots of errors beyond grammar and typos. Regarding Carrier Oscillator you need to first set the output level to 300mv and not 50 mv as the manual directs. Step 4.5 which uses Audio generator/wattmeter method is not very well written.

Some people believe there is only one way to adjust the SSB frequency response and that is by injecting mv level audio into mic line and setting the 3dB roll off on external wattmeter equally at 300hz and 2800hz. It is a good method but not the only method. Here are some methods you can use :

1. Some actually adjust TC-1 and TC-2 by ear. I dont recommend it.
2. Use the Marker and S-meter method. You can find this procedure in the TS-830 Survival guide. It works pretty well. Just remember to use Fast AGC and lite touch on VFO knob.
3. Use AF sig gen and external wattmeter method. Described a little better in the TS-830 manual than it is in the TS-820 manual. Essentially you load in CW mode to max out. Inject 5mv to 7mv at 1200 to 1500 hz into mic line and set Mic gain for 50 watts output (you use 50 watts for less stress on the rig as you will have some key down time making the adjustments). You then adjust the AF sig gen to 300 hz and 2800 hz and adjust carrier osc trimmers for half power at each end of the range.
4. Use an Audio spectrum analyzer software and a lap top and Rx noise bridge. Can be done without noise bridge if you can pick a time on dead band and clear frequency. I use a Palomar noise bridge and Spectro-gram. It is very easy and fun to see the pass band. My favorite and preferred method.
5. Use a RF spectrum analyzer (average KW hybrid owner doesnt own one)

There is nothing you can hurt and easy to change if you dont like the response. Since I run barefoot I tend to set my response a little higher than the typical bass response that KW hybrids are noted for. Worse you can do is get it sounding too thin and if you do easy to adjust.

Topic: 47069 Message: 47075

Byron:

Couple of additional points that may be obvious to you?

1. You cannot do anything about the IF filter response curves. They are what they are. All you can do by adjusting the Carrier Osc trimmers is what point in that frequency response curve that you insert the carrier.

2. When I talked about the preferred method using a AF sig gen. If you do not have a higher end sine wave function generator with ALC controlled output or digital output level indication make sure that you measure the output level and adjust it on each end. If using 5 mv then need to make sure generator puts out 5 mv at 300 hz and at 2800 hz. This requires a good true RMS AF VTVM. I have this gear only because I have paying customers who expect the alignments to be done well.

3. When I said to adjust for 3 dB roll off or 25 watts at each end of the audio spectrum you may not get 25 watts (precisely 1/2 power). More importantly is to adjust for as close to 1/2 power at 300hz and 2800hz or whatever values that you chose. That may be 30 watts or it may be 15 watts. Just adjust trimmer cap for the same lower level wattage at each end. If you do not have an external wattmeter you can use an RF probe and VTVM and measure RF voltage across your dummy load.

4. If you want to see what Spectro-gram looks like there is a sample in the Files section under the Repairs/Alignment tab. It is not as good a sample as it could be as it was taken without using a diode noise bridge and just used off air signal on 40 meters, but gives you an idea of what it looks like. You can set the high and low freq markers anywhere that you want. You will note that this response curve is shifted a little high. There are lots of FFT audio spectrum analysis software out there. I settled on Spectrogram as a free version was available off W5BIG website.

Good morning Terry
First, I have to thank you for taking the time to answer.

To answer your number one Q, yes, I have full output, measured with Bird.

Number two, yes, also correct (the third band switch position on 10m seems not to work, but is of no interest in this case) I hope.....

Number three, my friend, the owner has got one, and I will take rig over to his place later today hopefully

Number four, as far as I understand, (and that's not a lot, I know) the coil pack consists of 4 sections, osc coil unit, mix coil unit, ant coil unit and drive coil unit....

Now, this is a very stupid question, but the heterodyne crystal oscillator, is that the same as osc coil unit?
Of course it would be for the 28mhz, am I correct?
If so, have only tuned it by ear, and like I say, the receive works just fine (except third switch poss)

If you have a number on TP-3 on the RF board, of what its supposed to be, it would help.

Terry, I really do appreciate your help, and I do realize that Im out on thin ice, but will get back to you, as far as we have checked TP-3, but if you in the meantime have a suggestion, Im looking for it

Thanks in advance

Lars

OK I am still not sure I fully understand the problem.

What I think you are saying is that on all bands with exception of 10 meters you have normal RF output power level at all positions of the VFO dial for a given bands allotted frequency range. On 10 meters band you have normal RF output when the VFO dial is above 200 and the RF power drops off when you turn dial below 200.

Yes the Het Osc is same as the Osc coil board.

It is not likely the problem has anything to do with VFO output or Het Osc output level, but I would check both on 10 meters below 200 on VFO dial to make sure to spec. I would think if VFO output level was falling off below 200 on the dial it would then affect all the bands and not just 10 meters.

Need RF probe or O-scope to do that. Measure on the IF board at VFO input. Should be approx 1.0 rms rf volts across full rotation of the VFO dial. Measure Het Osc level at TP-3 on RF board and it should be approx 800mv to 1.0 volts. If not repeat the adjustments. Dont leave set on the peak of the Het coil as oscillator may not reliably start each time you switch back and forth.

After that the best thing to do is measure the RF drive level to see where you first see it drop off at as you run the VFO below 200. You can do this in CW mode with the SG switch turned off. At TP-2 on the RF board you can measure the TIF input signal. It should not be band switch dependent. Should be approx 200mv regardless of VFO setting.

Next can measure at TP-1 on RF board. This is the output of the TX Mixer and it is somewhat band switch dependent. It is produced by mixing the TIF signal with the band specific Het Osc signal. Should be approx 2.0 rf volts.

Next to measure output at Plate of Driver tube and control grids of 6146 finals you need a 3 diode probe like a Heath PK-3 or a RF Millivolt Meter or O-scope as the levels are too high for a single diode probe.

It is possible there is a problem with 10 meter Mixer tank circuit or Drive tank circuit and associated band switch contacts. Also the Driver tube plate chokes and 6146 plate chokes could be coming in to play.

Really cant tell until you do some RF drive level measurements to see where the levels fall off at below 200 on VFO dial.

Topic: 46768 Message: 47079

If I may add a comment or two to Terry's response about the various VFOs in the TS-520, 820, 530, and 830.

A common misconception by some hams is that the KW Hybrid internal and external VFO frequency range changes when the band switch changes. That's simply not true.

The TS-520/TS-820 internal and the remote VFO-520 and VFO-820 operate over a frequency range from 4.9Mhz to 5.5Mhz.

The VFO-520 and VFO-820 are the same VFOs that are in the 520 and 820 transceiver.

Also, the VFO-520 and the VFO-820 are interchangeable between the 520 and 820, no mods required, both are "Plug and Play" between the two transceivers. That means you can use a VFO-520 plugged directly into a TS-820 without any cable or VFO changes. The same applies with the VFO-820, it can be plugged directly into a TS-520 without any cable or VFO changes.

The TS-530/TS-830 internal VFO frequency range is from 5.5Mhz to 6.0Mhz.
The VFO-230 frequency range is from 5.4Mhz to 6.1Mhz
The VFO-240 frequency range is the same as the TS-530 or TS-830 internal VFO frequency range, 5.5Mhz to 6.0Mhz.

The VFO 240 is the same "analog" VFO that's in the TS-530 and TS-830.
The VFO-240 receives power from the TS-530 or TS-830 through the remote VFO connecting cable plugged into the rear read panel's VFO DIN socket.

The VFO-230 is a digital VFO which has it's own built in power supply.

The VFO-230 and the VFO-240 are not compatible with nor will they work with the TS-520 and TS-820.
The VFO-520 and the VFO-820 are not compatible with nor will they work with the TS-530 and TS-830.

Pretty odd in a Het Osc rig for rf output power to vary with the VFO setting. Can happen with a PLL rig if VCO level is varying at each end of the VFO travel.

It is sounding more and more like a band switch problem, but only way to tell for sure is to measure VFO and HET LO levels and confirm to spec and then run the TX Level Diagram. Since 20 meters is working well I would run and record RF drive levels at TIF, TX Mixer output, Drive tube plate output, and 6146 control grid input at 14.200mhz. These should be close to those noted in your service manual. Always good to have these measured and recorded when rig is working as it should. Helps with future troubleshooting.

If Mike or someone else has any ideas please jump in and help here.

Mike:

Regards common misconception:

I was talking about VFO output level and not frequency. I know VFO output and frequency have nothing to do with the band switch position.

Since he reported output power dropping below 200 on the VFO dial I thought good idea to first make sure he had good spec VFO output level from 0 to 500 for good LO mixing action at the TIF Mixer. VFO level has nothing to do with band switch, but could have a low level and not be as big a factor on the lower bands.

A low level TIF could result in lower output from TX Mixer which would be more of a pronounced problem on 10 meters than the lower bands. Couple that with low 10 meter Het Osc level and RF drive on 10 meters could be low.

I just wanted him to make sure he had good VFO output level from 0 to 500 and to confirm he has it on 10 meters where the output problem manifests itself even though the VFO doesnt know what band rig is on.

47082. KENWOOD HYBRID NET UPDATE (January 19, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-19 19:37:55 UTC
From: Mark Gilger
Topic: 47082 Message: 47082

```
Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm
```

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

```
The Saturday 40 meter net had 11 stations
checking in under good band conditions. There
were 2 new stations checking in, WA1FFT, and
N9JR.. We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
3 running TS-820(x)
0 running TS-830S

I was running my TS-940s with an L4B amplifier.
```

The Sunday□s 20 meter net had 17 stations
checking in under good band conditions. There was
7 new stations checking in, VE7BGJ, NT9M, KB5NBJ,
KB1ZIQ, K6HRU, AE5DW, and KD7DPK. Out of those, there was:

```
5 running TS-520(x)
1 running TS-530(x)
4 running TS-820(x)
4 running TS-830S

I was running my 820 twins, TS-820s + R-820.
```

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

```
If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
```

would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 51, Sunday☐s total = 60 (Month to date)

Net Info:

47083. 820S VFO Rebuild and vias resolder, Band switch sprocket

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-19 12:44:00 UTC
From: Michael Sylvester
Topic: 47083 Message: 47083

The radio that went up for raffle last week (3 weeks long raffle to support Patriot radio, The Micro Effect .com) is working excellent. It had no dig display and no receive 2 weeks ago.
It does need the smaller bandswitch sprocket on the wafer shaft though. Right now it's sporting an abundance of JB Quick metal epoxy, 6 or 8 layers, extending an inch down the shaft, before it was solid. After exhuastive study of the 2 detents under magnification, one in front at the switch and one in the HV cage, both are centered and in line. They are quite worn and both have side play.
The wafers were out of sinc and it was a pain getting the shafts from RF board to HV cage in line when I had no functional set screws on the darn bandswitch upper sprocket. I spent hours putting many coats of JB on that buggered up sprocket to the shaft before it was rock solid, AFTER I WAS 100% sure I had detents centered and all wafers in line. It was quite buggered from a wiped out plastic coupling that was also replaced, loctite on all 4 set screws.
Man, talk about a soft bandswitch, was real bad with a coupling slipping and the 2 detents out of alignment. She's tight and crisp now.
Anyone have a set of black sprockets laying around (or white for that matter) let me know, chains too.
(I'm buying those 820S units that are piling up in the corner.)
I've found new much cheaper couplings that I might offer, need to test them first though.
I found that the set screws from the old plastic couplings are same threads as sprocket screws, set screws are harder, taller threads, less prone to fail being grade 8, if the screw holes weren't already gone I could've used those to lock it down.

If I were making them I would go with a thicker collar so as to have more threads, less likely to strip out. with grade 5 screws or even better, hardened set scews.
I also note that there is the smaller black set and a larger diameter white set of sprockets. I think the same rotational torque levels are present at the lock screws so no change to the stripping issues were achieved.
Unless they went with a thicker collar for more threads, 3 or 4 set screws instead of just 2, no improvements were realized. Different pull forces are being put on the chain with the larger sprockets however.
Are the smaller black and the larger white sprockets interchangeable?
I should think so, the only constraint would be the need for a longer chain for the white.
If switching from the black to white you will need the matching chain or be real good with wire and needle nose.
I'm not sure if other components would be in the way to prevent switching from BL to WH, I have both but didn't check.

It would appear that I can now rebuild the 820S VFO. I did an 820 VFO first, don't have a radio to put that into however.

I find in the rebuild of VFO that temper is gone in the spring, the source of the problem of VFO issues.
2X now.
I also note that if it is "self lubricatin phosphor Bronze" it is however chrome plated.

There is corrosion at the mechanical electrical connection point on the shoulder of the variable cap shaft and on the spring surface.
Being different metals, some electrolitic action will occur (corrosion).
I also note ON BOTH VFO's that I've done that there is a green substance remaining on the cap shaft in this area.
I believe this to be "Oxiban" a greasy copper based anti-oxidant that was used extensively in industry during that time period. It is hard and unprotecting after 35 years.
After removing knobs, faceplate, VFO comes out.
Disassembly, rebuild by cleaning, lubrication of bearings with fine grade white lithium grease, re-arch and removal of much of the chrome plating of the spring, a different electrical connection than original stock, a bit of reshaping to my specs, reassemble.

After installing both my first Vias board and Rebuilt VFO,
VFO is rock solid. I also now understand the vernier and have a handle on that.
Kinda nice to see a solid 820 Digital display and vernier working perfectly and the 25KHZ marker is dead nuts on,
while matching the vernier too.

Is there such a thing as a DVD for play on television for a man that wants to get his ham ticket but can't see well enough to study a book and doesn't do computers?
The man's mane is Hubert Schmidt, lives in Lynville, TN.
Anyone in that area that would be willing to help an aging man get his ticket? If so contact me please, off group, personal email. (He can't read because his sight is failing, he asked me if there were any DVD study discs).

I will be posting on eBay 2 linear amps this week and one station monitor. LA-1000 and LA-1000A
SM-220 station monitor in real good shape.
I may have another 820S refurb, detailed, VFO rebuilt, Vias solder fix,
my "you can't do that" wafer refinish,
up for sale on eBay in a week or so.

"An Ill wind Blows"

Hello again
Life has a way of get in the way of fixing radio....
Well, anyways, just saw latest answer Terry, took my own external VFO, that I know works, but same result, so out ruled low VFO output

Still haven't done more, and now tired of even see the rig

Will get back as soon as urge comes back!

Thanks again for now!

Lars

Ok when you get time I would run TX Level diagram to see where you are losing the RF drive level at. My guess is that TIF input to TX Mixer is OK, but I would still measure and record it.

Will be interesting to see what the output of the TX Mixer looks like. Again it should be something on the order of 2 volts. You can measure that with a standard one diode RF probe and VTVM, but do not attempt to use that probe to measure output of the Driver tube or the control grids of the Finals. The PIV of the diode is not high enough and it will be damaged.

Hello Group,

I am in the process of adding some AM gear to my station and have two TS-530 SP's in very good condition that I will be letting go. Serial no's are 4080348 and 6050040. I thought I would offer them here before going to general public. If you are interested, send me an Email off group and I will send pitures and particulars. I would like $350 each plus shipping but am willing to take offers this week. If no interest here I will be taking them to Dalton Hamfest or Ebay. These rigs were not functioning when I got them and I did some service work on both. So you know they are not previously owned by a little old lady who only used them to check into the net on Sunday nite. Seriously, they are in good condition.

Topic: 47087 Message: 47087

Hi All,

I have acquired a 830S that has been in storage for quite a while, it was placed in storage when it lost its transmit, according to the son of the owner (now SK). The previous owner had started to carry out repairs/refurbishment.

On a visual inspection of the boards this is what I found.

On the Final Unit (X56-1380-00)

R 2-5 20 ohm Resistors removed

R 7-8 100 ohm Resistors removed

These have now been replaced

Rectifier Unit (X43-1370-00)

R 11 470ohm Resistor Removed

R 15-16 56K Resistors Removed

These have now been replaced

In the Final Cage C7,C8, L1 were removed, these have also been replaced.

These were obtained from The Hybrid Store

Relay RL1 was also removed -this has been replaced (Hybrid Store)

A known good pair of 6146b and a known good 12by7a were installed.

On powering up the 830 receive is working fine on all bands.

On Transmit the following occurs

IP SSB key down adjust for 60ma

Tune,ALC unable to peak the drive, there is no real deflection on the meter.

Meter moves about 1mm on key down.

SG switch is on.

HV reads 900V on Key Down

I have measured the voltage at pin 3 on the tubes I get 123VDC on RX 118VDC on TX same on both tubes. I am sure I should get 265VDC at pin 3.

Band switch has been cleaned using de-oxit.

The band switch plastic coupling has a slight crack at the allan screw, but it is turning correctly I will change this shortly.

So please any ideas suggestions where to go next will be greatly appreciated.

Regards

Keith,

It does appear the final tube screen voltage is a bit low.

The Rectifier Unit's 210A supply provides plate voltage for the driver tube on the RF Unit board plus screen voltage to the final tube screen through the Final Unit's "SG" terminal. If the Rectifier Unit's "210A" supply output voltage is low then the driver tube's plate and final tube screen voltage will be low.

The filter capacitors for the 210A supply are C180 and C181 on the IF Unit. You said you replace R11, 470 ohm 1/2 watt resistor.

Sounds like you have lost one of the filter caps in your Screen grid supply or you have a bad/dirty molex Connector 14 on the IF board. I would gently rock and/.or un-plug and re-plug Conn 14 as a first step.

It is a C-R-C Pi-filter (C180, C181, and R11). You replaced R11 and the filter caps are located on the IF board. You can buy replacement caps from Ken K4EAA. I would replace the 300 caps also (Driver tube anode supply) while you have the board out.

This means reduced screen grid voltage on the Driver tube so RF output will be low. Need approx 47rf volts and -60vdc bias on 6146 control grids to get ALC indication.
Screen grid voltage of Driver tube Pin 8 should be approx 215-220vdc (schematic is wrong) in TX mode. Its RF output will be very sensitive to screen grid voltage.

If you have a multi-diode RF probe or an O-scope or RF millivolt meter you can measure the RF drive voltage at Pin 5 of 6146 finals. As mentioned it needs to be approx 47rf volts. Measure it with CAR level pot at approx 1200 position.

Date: 2014-01-21 03:48:03 UTC
From: Byron
Topic: 47090 Message: 47090

Hello- I have a DG-1 that will only register a 0 or a 4 or an 8 in the tenths of KHz digit (the far right digit). The VFO tunes very smoothly, and as I slowly tune through a carrier I hear the beat note change freq and watch the display change from a 0 at far right to a 4, then to an 8, then back to 0 as I move up one KHz.
I swapped a known good DG-1 module into the TS-820S (everything else is working fine) and the problem went away.
Would this issue be one that may possibly be cured by re-soldering the plated through holes in the digital board in DG-1? I was studying the write-up on doing this. Thanks for any suggestions, Byron WA5THJ

Just to confirm, R11 was replaced with a 470 ohm 1/2 watt Resistor.

All 4 caps have now been replaced on the IF unit. No difference in original fault.

I forgot to add something on the original post, which is. When the mode switch is switched CW/USB and USB/LSB the RL1 Relay (AF Board)activates it does not "chatter" just activates once.

Any further suggestions measurements will be carried out tomorrow after work.

I forgot to mention would not use a 1/2 watt resistor for R11. I would use at minimum a 1 watt metal film resistor.

Screen grid current contribution from the Finals and the Driver tube approaches 30 ma not counting 3 or 4 ma of voltage divider bleeder current for the Driver tube supply.

P = .030 x .030 x 470 = .423 watts.

For what it's worth, Stock Drive Products has metric ladder chain sprockets that may work for the Hybrids. Available materials are brass, acetal and stainless.

Here is link for online shopping:

https://sdp-si.com/eStore/Catalog#

Select metric and scroll down to the ladder chain section. My 820 has 6mm bore and 4.8mm pitch with 12t black sprockets on the control shaft and 20t white sprockets on the individual drives. The black sprocket hubs have longitudinal cracks at the set screw holes.

For my TS-820S Drive control they do not stock an exact replacement (the pdf catalog does show an exact match), but the smaller sprocket is only one tooth off (13 v 12) and I think it would work. The ladder chain in my radio has a spring-loaded link that I believe provides tension to keep the control shaft in place and could probably stretch a bit to accommodate a 13t sprocket.

I have seen pictures of other model Kenwoods that have different size sprockets, so you'll have to open it up and visually confirm what you have.

They are not cheap, however, and I would try repairing the existing sprockets first, using one of the many ideas already presented.

A few days ago I repaired my severely cracked TS-830S sprocket wheels using Mark Gilger's simple, no-disassembly-required cable tie cinching method utilizing Loctite Epoxy Plastic Bonder (available at Home Depot). This is one of the few products I found that is said to work with notoriously difficult to bond Nylon.

http://www.loctiteproducts.com/p/13/7/epxy_plstc_s/overview/Loctite-Epoxy-Plastic-Bonder.htm

If the cable ties are snugged sufficiently, the cracks in the nylon sprocket wheels can be closed even with the set screws in place. The Loctite epoxy dries white so the repair is not unsightly at all. Theoretically at this point I could probably remove the cable ties but -- as they are also white and I took pains to orient them uniformly (boy - talk about anal, eh?) they don't look bad and may (or may not) provide an extra measure of security.

I will, of course, be among the first on the list for replica sprocket wheels should they ever become available, but Mark's terrific repair method is just the ticket in the meantime.

Topic: 47101 Message: 47102

Well, that's a matter of opinion and, to a certain extent, the individual radio's setup. I have a TS-830S and a TS-530S. Both transceivers carry their full compliment of filters.

For hard core CW in difficult conditions I usually prefer the 830 because its dual IF filtering and variable bandwidth tuning (VBT) help "dig out the toughies". But, for sideband my choice is the 530. Its receiver audio sounds just a bit cleaner to me with more headroom. Not that the 830 is bad, mind you, but the 530 is a touch more pleasant to listen to -- especially for long stretches.

On transmit (even though you didn't ask) both radios garner excellent audio reports. The RF processor on the 830 is more advanced that the simpler, 530 speech "enhancer" but I use processing very conservatively and sparingly, so I haven't noted any practical difference in the two radios' transmit quality.

It should be noted that the variations between the two receivers, slight though they may be, could be a product of my individual radios. My 530 arrived in much better shape and has required far fewer "renovations" than the 830. Plus, I just finished restoring the 830 and it has yet to receive a full, nitty gritty, re-alignment with a full array of test instruments.

73,

Craig

Hi all!

Thought I'd share a great find with the group...

Lowes has a spot on match spray can for the light gray case paint for the TS-820, etc.

It's under the brand name Blue Hawk (actually Valspar) with the color name "Gloss Smoke Gray" (number 0394616). A 12 ounce can is $3.98. ;)

73!

Bill - N7YGU

Bill,

The Blue Hawk is actually several shades
different than original hybid paint. I tried
that, any several others, including the match
that's sold on ebay, before I ended up going to a
paint manufacture here. I ordered 6 cases of the
correct match. I sold 5 cases on here to others
willing to split the cost with me. Of course it's
your radio, but I'm pretty picky and I did not
want something that was a couple shades from original.

I've also heard of guys taking their case to a
place like NAPA auto parts. Heard that they do
a good job of matching. You need to have them do
the inside cover though, as the outside has faded over time.

Good luck.

I match old paint all the time for various reasons, and any automotive paint store (I guess that could include NAPA, I think they sell Martin-Senour paints) will scan the old original paint and make a formula and mix as much as you want. The next question is the amount of flattener to add because the original was a satin finish, not a high gloss. It is very involved process, but worth it.

One thing worth noting, is that the Kenwood isn't all exactly the same. I got a new cover for my 820S from a group member a while back, and it was a slightly different shade than the old one. It was obvious both were the original paint.

On another note, (and this might have been intended as slightly different), my SM-220 is a third shade.

This is in CW mode and is positive 120vdc and not negative 120vdc?

Your 210A SG supply to the Driver tube looks good. If 210A is good then it should be supplied thru RL-1 relay NC contact to Mode Switch to SG1 thru choke L1 to PD2 to SG post on final board.

What is voltage on SG1 post on Rect Board? Maybe bad NC contact in RL-1?

What is the voltage at SG post on Final board in Tune Mode?

I have never seen bad RL-1 contact or bad Mode Switch contact or bad L1 choke.

Just need to measure voltage along the path from 210A post on Rect board to SG post on Final board to see where losing it at.

BSA 0791,

Please remember to use name\callsign at end of email.

I have both radios, whilst the 830 is double conversion and 530 is single conversion, and if aligned properly very little difference in recieve performance to the ear, in my opinion. 830s has some nicer features VBT etc.

Get both you know you deserve them

If you want to see measured receiver performance (noise floor, agc threshold, blocking etc) look at Sherwood Engr site. The TS520, TS820, and TS830 results are listed there. Unfortunately I did not see the TS530 test results.

As it has been mentioned the TS530 is single conversion and lacks the VBT function.

A full filtered TS-830 (with proper filter combination that optimizes the VBT function) is the better receiver for contest and CW operators when it comes to selectivity.

I think the TS530 is quieter and signals seem to jump out as you tune across the bands.

If I had to pick one based on receiver alone I would pick the TS830. If I was to pick one over all it would be a TS830. You will find some real passionate supporters of the TS820 as well.

If I had to pick one for receive audio quality it would be the old TS520. There is something about that old OTL complementary pair that sounds better to my ear than the IC chip audio amps.

Dave had best idea..... own a TS530 and a TS830. Of course both need to properly aligned before you can pass judgement as so many fingers have been inside most of them over the years.

Keith:

I am apparently being too cryptic. I think you told us that you had 256vdc on the screen grid of the Driver tube. If that is true then should have approx 256 vdc on 210A at the Rect Board.

If you have 256 vdc on 210A then it tells you that your SG supply rectifier and pi-filter are good.

So what I was suggesting is that you then make measurements in CW Mode only along the entire path to the Screen Grids of the 6146 final tubes from 210A on the Rect Board to Pin 3 of the 6146 final tube sockets. .

Assuming that 210A at Rect Board is good then the next place to measure would be SG-2 where you should still read approx 256vdc thru the Normally Closed contacts of RL-1 relay.

The next place to measure would be SG-1 on the Rect Board. Should still read approx 256vdc at SG-1.

We need you to look at the schematic and measure the voltage at transition or terminal points along the path and tell us what is the first place you do not obtain 256 vdc and first see 120vdc.

Places where you could be losing the voltage would be a bad NC contact at RL-1, shorted of greatly reduced resistance at R15/R16 Tune mode divider resistors. Bad mode switch contact etc. All places where could have IR drop.

I am probably not explaining it clearly.I dont know your experience level. Do we need to take one reading at a time?

I just jumped in as normally this is a relatively easy problem to find and fix.

I have to get back to my bench as I have to finish a TS830 and just got a TS530 that I need to start. I am sure Mike or others can talk you through this .

From: Jan Servaites
Topic: 47115 Message: 47115

My 830 is showing the same symptoms (from what I'm seeing out there with a majority of 830s) . There's got to be a common problem area here and I'm going to try to find it.
By the way, I have done the normal hybrid maintenance of HV, screen, & plate recap. Both IF & RF boards have been painstakingly cleaned (just the RF board took about 20 hours of time; Wafers are all good). Driver tubes have been swapped in/out with no improvement.

Terry, please post (if you haven't already) a list of areas/components to troubleshoot.
A lot of test equipment is available here, so I can proceed with any troubleshooting that you recommend.
Thanks
Jan N8CBX

Keith,

Do this. Place the MODE switch to TUNE then measure the Rectifier Unit's "SG1" and final unit's "SG" terminal voltage? Are both of them now "+254VDC"? If so then I the Rectifier Unit's "SG2" and "TUNE" Mode switch wires have been "switched".

Keith,

I say measure the SG1 and SG terminal voltage in TUNE mode because the +128VDC you are seeing on the Rectifier Unit "SG1" and final unit "SG" terminals is what you would see "IF" the MODE switch is set to TUNE.

Here's how you calculate the final tube screen voltage in TUNE mode. I provide this so you will see why.

The 210A voltage is applied to the voltage divider resistors, R15 and R16, both 56K in series to ground resulting in a total resistance of 112K ohms (56K x 2 = 112K). The total current flowing through R15 and R16 is ".00228 amps" (254 / 112000 = .00228) or "2.28ma". The voltage drop across R15 is approximately +127.68VDC (E = I x R or .00228 x 56000 = 127.68). This is the final tube screen voltage with the MODE switch set to TUNE. This also will be the final tube screen voltage in USB, LSB, and CW modes "IF" the Rectifier Unit "SG2" and "TUNE" wires have been switched and is very very close to what you are seeing at the Rectifier Unit "SG1" and final unit "SG" terminals. That's why I ask you to measure the "SG1" voltage with the MODE switch set to TUNE. You don't need to measure the driver tube screen voltage nor the Rectifier Unit's "210A" voltage, we already know they are what they should be. We are only concerned with the "SG1" voltage with the MODE switch set to TUNE.

The news is truly sad.

I had just become acquainted with Gordon very recently after he offered some valuable and friendly advice concerning a troubleshooting problem and donated a scarce part needed to effect a repair. It was this act of true kindness and generosity to a virtual stranger that spoke volumes about the man.

My condolences to Gordon's family and to those of you who were, I am sure, among his many dear friends.

I am not sure what thread you are referring too? Last I knew you were working on the AVR board. Are you saying that after cleaning the bandswitch contacts you have no RF output on any band and your receive sensitivity is down on all bands? Not very practical to clean bandswitch contacts in place. Also need to measure the resistance or IR mv drop across each contact to see if you did any good. Almost never bandswitch problem when all bands are low or missing.

I usually repair the receiver 1st. I assume you have all the required low voltage supplies (12 vdc regulated, 9vdc regulated, and RF-1 3.6vdc (AGC and ALC bus reference voltage).

I usually start on 14.2mhz (middle of the band range and where KW provided the RX and TX level diagram values in the service manual). You can do a quick check and use the Marker signal and see what S meter readings are on all bands with Drive Control peaked at 1200. Should all be very close to or slightly more than S9 on each band. If lower than that I would start by doing coil pack alignment. If very low or non-existent then may have a failure in the front end. (L41 and/or Q1)

If all bands are very low or no receive the most common problem is ESD (shot of nearby lightning) or accidental transmit RF burning up L41 ant step up transformer and sometimes Q1 RF amp.

You can inject 8.830mhz RIF at output of RF board TP-2 and if good loud tone and S-meter indication you know the IF chain, product detector, and audio are all good and problem is on the RF board (or interconnecting leads and molex connectors) .

Can just use RF sig gen and work from SO-239 or work back wards. Easy to get on the wiper of S1-2 and inject and if good Rx and S-meter you know Q1 RF amp is not hurt and problem is likely L41. If inject at TP-1 and no RX and inject at S1-2 and have RX almost certainly bad L41. On occaision can have bad BCB filter with L1 shorted to ground shunting rx signals but not often.

As far as low or no TX RF output on all bands it is not likely bad or dirty bandswitch contacts.

I would start by doing Driver stage test to prove have good RF drive available (need approx 47 volts at 6146 control grids for full ALC indication). Do the Driver stage test with SG switch off. CW mode. Drive control at 1200 and CAR level pot at 1200. Meter in ALC. Flip to Send and peak Drive control. If meter pegs FSD simply back down the CAR level. Repeat on each band with VFO around 200. If no ALC indication increase CAR to full clockwise and repeat. If the Driver stage is good should be able to get FSD on all bands and it should hold there and not drift off with rig keyed. Let Driver tube rest between each band as it is running Class A at max plate current so will get pretty hot during this test.

If you have no ALC indication on any band with the Driver test then I would break out the RF millivolt meter or O-scope and run TX Level diagrams starting with the TIF signal. Then move on to the output of the TX Mixer at TP-4 and then control grids of the finals. Where signal is lost then take DC voltages at the active device and make sure you have the necessary LO signals (at TX Mixer need Het and approx 1 volt of VCO as the LO).

Troubleshooting no RF output or low RF output is one of easier problems to troubleshoot especially if low or missing on all bands.

This is a lot to cover and as I say I almost always get the receiver going first and then move on to transmitter.

I had a TYPO.

At TX Mixer need TIF and VCO and not HET. Sorry about that.

On an O-scope TIF signal will not be a clean sine wave. Lots of harmonic action from VCO leak back. If your scope has filter capability may want to put in low pass mode. TIF should be approx 15mv rms or 42 P-P.

Output of TX Mixer (input to 12BY7A control grid) will be approx 2 to 3 rf volts depending on the band.

If you cant get on the Plate of the Driver tube you can get on the small plates of VC-3 top solder lug. Should see approx 58 to 60 rf volts. This is just after C29 .01 blocking/coupling cap.

At control grids of finals should see approx 47 to 49 RF volts. Should have approx -60vdc bias offset for max ALC indication.

47128. TS-520S Low Drive on Higher Bands

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-23 21:15:29 UTC
From: Byron Tatum
Topic: 47128 Message: 47128

Hello-

I am going through a nice TS-520S and reached the RF Alignment steps. I have good finals in it and driver tube. The receiver is really working well and the receiver RF board alignment went fine. I was catching the driver coils, as I always do when doing a TS-520S alignment, while I was peaking the receiver coils. I cannot develop any ALC voltage on 15 or 10 meters, I get plenty of ALC on 160 and 80, a little less on 40 and I can definitely tell I am having to struggle 20 meters. I can get about 50 watts output on 15 meters and around 30 watts output on 10 meters, but no ALC voltage showing in CW mode. I did notice, at the instant the unit is placed in SEND in the CW mode there will be a short spike upward of ALC on the meter.

I thought I would ask before I go any further - am studying the operating and service manuals. I noticed there are a number of coils/RF transformers used in TX mode, located on RF and IF boards, that are not covered in the alignment instructions.

Thanks all, Byron WA5THJ

47129. FS- Nice 1.8 Khz B/W SSB Filter for TS-520(S)

Hello-

I removed a nice 1.8 KHz bandwidth SSB filter from a TS-520S, it is made by TAMA Electronics in Tokyo. The filter worked fine, it is just a little too tight for my liking for casual ragchewing. I replaced it with the Trio YG3395-S standard SSB filter that I had as a spare. The carrier osc's required only a very slight touch-up, so that tells me the TAMA filter has not shifted or became defective.

I would like to trade this filter for a 0.5 KHz B/W CW filter for the TS-520(S), YG3395-CW or equiv.

Thanks, Byron WA5THJ

Keith,

What did you say the voltage at the Rectifier Unit's "SG2" terminal is, not the SG1 terminal? Is it the same the SG1 terminal's +124VDC?

Also have you check the Rectifier Unit's connection from the 210A through the Rectifier Unit's relay RL1 to the Rectifier Unit's "SG2" terminal?

I can't see any possible way, unless there's been some wiring/circuit board changes on the Rectifier Unit, where the SG2 and SG1 voltages are not +254VDC with the MODE switch set to USB, LSB, or CW modes! I can understand the SG1 voltage reducing by 50% with the MODE switch set to TUNE but not in USB, LSB, and CW modes!

Mike:

I was trying to get him to read the IR drops as he is able to power the circuit instead of taking resistance readings. I struggled teaching this to industrial electricians who thought you had to get everything dead and use an ohm meter to tell if a contact was open or closed and how well closed. .

I assumed radio was working correctly and then failed. I did not think that he or previous owner had rewired the mode switch. Stranger things do happen.

At this point assuming that what he reports is accurate and the radio was on my bench I think I would read IR drops from 210A to SG2, SG2 to SG1, SG1 to PD2 and so on.

A real puzzle and something that could probably find in minutes if could get hands on it.

This media can be a blessing and a curse!

I assume you have tried with the CAR level pot full CW?

Do you have an RF probe and VTVM or an O-scope?

If so, load to maximum on 15 meters. Then measure the RF drive voltage at MD on RF board. It should be approx 2 rms rf volts or 5.8 P-P. This is the output of the Transmit Mixer.

You need a multi diode probe to measure plate of Driver tube and control grids of the finals.

If you want to see normal TX Levels then run them on 20 meters and record them so you have base line for reference. Start with TIF signal at TP-2 and work toward the finals control grids. Will need an O-scope to measure TIF as it is too low for RF probe. Will be around 200mv to 250mv.

ALC indication is a result of ua grid current flowing from the 6146 control grids back to the -C supply when the positive going half of the RF drive voltage exceeds the operating bias voltage.. In a TS-520S you need approx 46 rms rf volts on the control grids of finals for full scale ALC indication. Assuming approx -55vdc operating bias for 60 resting plate current then any RF drive less than approx 39 rf volts means no ALC indication. You will have RF output power just no ALC indication.

You cannot measure the RF drive at Plate of Driver tube or Finals control grids with a standard single diode RF probe as it will exceed the peak reverse voltage rating of the diode and burn it out. This is why Heathkit made the PK-3 probe with 3 diodes in series to allow just such testing.

Give an example of coils used in TX mode that are not adjusted in the alignment procedure. Only ones you may not be doing that I am aware of are band pass filters which require Sweep generator which average ham may not have.

hola Arnie,

It is not hard. Power OFF and rig un-plugged. Remove top and bottom cover. There are 3 screws on the right side of the chassis and two on the inside. Move aside the wire harness..you will see them. I find it easier to also remove the AF-AVR & the Relay Unit. It makes is a little easier to get the PLL Ass'y unit out. There are 5 connectors to the PLL unit..mark them for position..for easier replacement...but after many years of being in the same position...that may not be a problem. It is up to you whether you want to take apart your replacement unit and clean the between board connector pins. Reconnect all connectors...etc. Check for proper operation, before you button it all back up. You may need to check/adjust the unit per Service Manual,
page 52, section 5-2.

Remember, you will be working around the bottom of the HV capacitors...make sure they are discharged/bled off!!

Also, I try and listen to your show and other Radio Havana programs on shortwave when ever I can.

Keith,

Has there been any repairs performed on the Rectifier Unit and/or the Mode switch, either by your or a previous owner that you are aware of?

Has this been a problem from the time you purchased the 830?

There is no reason for the SG1 voltage to be 50% less than the SG2 with the Mode switch set to USB, LSB, or CW. The only component between the SG2 and SG1 terminals is the "Mode" switch. The only time the SG1 voltage should be 50% less is with the Mode switch set to TUNE. This is clearly shown on the 830 schematic which you should be using to troubleshoot this problem.

Now HERE's an esoteric question the answer to which requires no fiddling with exotic test gear:

Has anyone found a suitable replacement for the internal speaker grille cloth found under the lid of our hybrids?

In repainting my KW cases thus far, I been able to successfully remove, clean and replace the existing grille cloth. However, the cloth on my latest 830 is so thoroughly and robustly glued that I am afraid it will not survive removal intact. I would like to find a substitute material that at least resembles the original. I have considered black pantyhose mesh perhaps sprayed with clear lacquer to stiffen it, but that's far different than the ultra thin felt or whatever that Kenwood employed.

Any ideas?

Thanks and 73,

Craig

Keith,

There is nothing wrong with the Rectifier Unit's 210A supply so don't mess with it!!

I'm still puzzled why the Rectifier Unit's 210A terminal has +254VDC on it but the Rectifier Unit's SG2 terminal has +124VDC. The only component between the Rectifier Unit's 210A terminal and the Rectifier Unit's SG2 terminals is the RL1 relay. Therefore, perform the following voltage check with your DC volt meter.

Connect your DC volt meter's RED meter lead to the Rectifier Unit's 210A terminal and the DC volt meter's BLACK meter lead to the Rectifier Unit's SG2 terminal and tell me what the meter displays.

I believe spraying any fine-meshed fabric with a stiffener will reduce, if not eliminate, its acoustic transparency.

As Butch, K0PSA, suggests, a fabric store should have something suitable for such a small area. I used a thin black fabric years ago in front of a perforated metal grill to improve the appearance.

Also try looking at Amazon and Ebay. I did a recover for a speaker for my sons large guitar cabinet from one of these. Can't remember who. They may send you a free sample as your needs are so small. Google speaker cloth for more choices.
Hope this helps?

I'm really sorry to hear this. Since I've had my TS-530SP Gordon's site has been my manual for the rig, in fact I don't think I'd ever even downloaded it but just kept opening the file off his site each time I needed it.

It's a shame to lose such a great resource and contributor to the community.

Hopefully his site will stay up but I know it can be trying for a family to deal with the all details that result from the loss of a loved one. Gordon's archive of Kenwood manuals is invaluable to the community. I don't have a good website to host such content on myself but I have made an archive of Gordon's files and am sharing it here:

https://docs.google.com/file/d/0B_nx4oLYGQ_KM3RjazV2UF9SRlU/
https://docs.google.com/file/d/0B_nx4oLYGQ_KM3RjazV2UF9SRlU/

If others in the community would please download a copy to help preserve his work that would probably be good. The total zip file is about 905mb.

Thanks.

73 David

Craig,

 If you have not already, visit a local fabric store. They have LOTS of various fabrics that will meet your needs, or any good "arts & crafts store." My lovely XYL..took a sample and found an almost exact match. It was just a bit thicker..but just as porous as the original. Did not seem to muffle the sound...but I use headphones most of the time anyway If you are married...take the XYL...she'll think your the best!

I had a robustly glued one on an Icom-735. WD-40 on a q-tip softened the adhesive. I was able to easily remove it by sliding the blade of an exacto knife under it and using the flat of the blade to lift it up.

After it was removed I washed it dish washing soap and water and dried it between two paper towels.

I'm investigating putting all of Gordon's
documents on my site. Depends if there is enough space. I should know shortly.

I had a lot of links that took people directly to
his site for manuals, etc. that soon might not be able to do that.

http://wb4hfn.com/KENWOOD/KenwoodHomePage.htm

I suspect there will be enough room, just need
some time to send files to administrator for
posting. I'll have more on that later.

Good advice, Joe.

To your point, my XYL was pleased some months ago when we visited Jo Ann Fabrics to select a small quantity of organza silk. I was in need of this particular fabric to fashion internal windscreens for my homebrew ribbon microphones. The downside was the fact that my intended five minute trip became a two hour-plus affair as materials for new curtains and re-upholstery jobs were being considered. This is nearly as deadly as a ladies' shoe shopping excursion through a mega-mall.

Still... I'll do it!

I can host anything up to about a hundred gigabytes without any changes needed. More than that will require that I actually shut down long enough to mount this terabyte hard disk in my server rack....

If there is any desire for a mirror of his site, and I think with a suitable memorial / eulogy at the top aimed at the people he helped on this list (and perhaps in Ham radio in general) at the top.

If there is interest in putting it up on my ftp/web/etc server, just say so.

Many thanks for all the suggestions. Good stuff.

I restore old broadcast receivers from the '20's, '30s and '40s so I am very familiar with speaker cloth, especially the reproduction varieties offered to we antique radio buffs. As you know, the grille material used by Kenwood is, as Butch pointed out, a stiffened gauze-like material rather than speaker cloth as such.

I will, as encouraged, haunt such venues as fabric shops and arts and crafts stores until I find what I am looking for. I'll pass along the particulars. Of course, if Bill Houghton's WD-40 on a Q-Tip removal method works, I will be spared the trouble.

Craig,
Try local auto dealer. I know the one I retired from at any time would have
many 6x9's to be returned on warranty. Most have nice material on them that
can be cut off. Did this myself recently, just went by and hit up ole
buddies in the parts warehouse, free is nice too :>D

I purchased the TS830S 30 years ago. Just got back into ham radio. It has been in its original carton for that period of time and never used. Just put up an antenna, set up the transceiver. Receiver and associated functions perform flawlessly. When tuning up the transmitter, however, there is zero drive registering on the meter. There is current registering at the final amplifier tubes but that is it. I pulled the 12BY7A driver from my TS520 which is functioning and no luck.
Any thoughts about next steps/

Tim,

You can tune the transmitter in CW mode but be warned that the final amplifier is operating at full power in CW mode. Set the meter to IP, connect the 830 to a 50 ohm dummy load, set the CAR control so it points between 9 and 10 o'clock, set the LOAD control fully CCW (knob pointing to 9 o'clock), Mode switch to CW, and flip the SEND switch UP. If you have a CW key plugged into the rear CW socket press the CW key and adjust the DRIVE control for a peak IP meter indication, otherwise if there is no CW key plugged into the CW socket, adjust the DRIVE control for a peak IP indication and quickly adjust the PLATE control for a dip in IP meter indication. If your dummy load has a watt meter then you should see RF indication. No watt meter, set the 830's meter switch to RF and you should see a rise above zero indicating RF is present at the antenna connector (SO-239). If this is what you see then I suspect resistors R15 and R16, both are 56K 1/2 watt, on the Rectifier Unit, have changed values to a point they are significantly out of tolerance, replace them.

If the radio has been out of service for "30 years" (wow), place heater sw to on and let it warm up for a few hours or most of the day, and then try to transmit again with low power setting. If nothing, let it cook some more.

Never heard of tuning that way Mike. Would that only apply to CW tuning or only in test situations or would that be a deviation from book tuning that has advantages? Explain please?

Michael:

90% or more of all boat anchor rigs are tuned in CW mode. They have no reduced screen grid voltage position or Tune position. If you grew up in the 50s and 60s and owned any of the classic Heath, Knight, Eico etc Class C CW rigs you would have loaded in CW mode with full screen grid voltage.

As Mike points out all you have to do is tune tank quickly to resonance so you do not have high off resonance plate current. If you leave the Plate Load cap plates meshed even lower plate current to worry about. Truth is it is pretty hard to exceed the plate dissipation loading in CW mode unless you flip to Send and walk away.

I mis-spoke when I said no Tune position. They do have a "Tune position" but it was more commonly used to allow tuning of the buffer stage and spotting the transmitter. It wasnt there to provide reduced screen grid voltage to the final tubes.

Hello Terry-
  Thank you for the very nice response and info! I have not been able to get back to checking out this TS-520S, but I did want to respond to you and tell you thank you.
  I do have a good scope and a VTVM with an RF probe.
 I have been studying the manual and what you mentioned so that when I get through with this set of 3 days out at work I can get back to troubleshooting the TS-520S.
  At first I thought possibly the 250 Hz CW filter may have too much attenuation, but when I go to SSB the drive level/RF output is still low.
  I will let you know what I learn, thank you, Byron.

Subject: [TS-520_820_530_830] RE: TS-520S Low Drive on Higher Bands

I assume you have tried with the CAR level pot full CW?

Do you have an RF probe and VTVM or an O-scope?

If so, load to maximum on 15 meters. Then measure the RF drive voltage at MD on RF board. It should be approx 2 rms rf volts or 5.8 P-P. This is the output of the Transmit Mixer.

You need a multi diode probe to measure plate of Driver tube and control grids of the finals.

If you want to see normal TX Levels then run them on 20 meters and record them so you have base line for reference. Start with TIF signal at TP-2 and work toward the finals control grids. Will need an O-scope to measure TIF as it is too low for RF probe. Will be around 200mv to 250mv.

ALC indication is a result of ua grid current flowing from the 6146 control grids back to the -C supply when the positive going half of the RF drive voltage exceeds the operating bias voltage.. In a TS-520S you need approx 46 rms rf volts on the control grids of finals for full scale ALC indication. Assuming approx -55vdc operating bias for 60 resting plate current then any RF drive less than approx 39 rf volts means no ALC indication. You will have RF output power just no ALC indication.

You cannot measure the RF drive at Plate of Driver tube or Finals control grids with a standard single diode RF probe as it will exceed the peak reverse voltage rating of the diode and burn it out. This is why Heathkit made the PK-3 probe with 3 diodes in series to allow just such testing.

Give an example of coils used in TX mode that are not adjusted in the alignment procedure. Only ones you may not be doing that I am aware of are band pass filters which require Sweep generator which average ham may not have.

Let me know if there isn't. It can't be *that* big, not more than a couple of GB. If you want some space I can probably donate some.

If you wanted to get hosting specifically for it, these days you're probably as cheap getting a VPS and having full control of the system than getting "shared webhosting" and dealing with someone else's idea of a "control panel".

> I had a lot of links that took people directly to his site for

No reason why you can't point the DNS at your server, and either place the files in the correct place or set up redirection. If I was hosting a backup of the site, I'd place it in a path like http://gjcp.net/~wb4hfn/KENWOOD/KenwoodHomePage.htm but obviously if you've got the whole thing up on another server you just make it work exactly like it did before.

The difficulty there is that you'd need to approach Gordon's family about control of the domain name, and of course you'd need to do that very tactfully. I don't know if you've noticed, but radio amateurs are a funny bunch, the RF gets into your brain or something, and we're not necessarily great at tactful.

Jan and Tim,

As Terry said, you can't "cook" or "getter" the 6146 final tubes by powering them up and letting them sit in standby (receive) for long periods of time.

The "getter element" in the 6146 and 12BY7, as well as other low power receiving and transmitting tubes, is attached to the plate (anode). The plate must heat up to a high temperature before the getter element can perform it's function. The only way the getter element can perform its job is for current to flow in the tube causing the plate to heat to a high temperature. The filaments of these tubes are not coated with a gas absorbing substance and the filaments cannot heat the plate to the high temperature required for the getter element to do its job.

The tubes that have a coating on the filaments are tubes such as the 4CX250s, 4CX300, and 3CX1500. These tubes have a "warm up" period that must be followed before switching the tubes from cut off state to conduction state. Failure to follow this "warm up" period can result in arcing within the tube which can permanently damage the tube. The warm up period for these tubes is defined in the manufacturer's tube specification (see the tube manuals for these tubes).

There are some "diode" tubes such as the 866 and 3B28 for example, that are named "Mercury Vapor" rectifiers. These tubes have a "warm up" period that must be followed before HV is applied. The "warm up" period heats the inside of the tube by the filament, "vaporizing" the small amount of "Mercury" in the tube, hence the name "Mercury Vapor". When HV is applied the "vaporized Mercury" glows a "light blue". Failure to follow this warm up period can result in an ARC to occur in the tube which can lead to damaging the power transformer and other power supply components.

Tubes such as the 833, 4-400, 3-500Z, and 4-1000 for example, do not have a "getter element" but rather the plate has a "gray dusty" coating. The coating is "Zirconium", a substance that, when heated to a very high temperature, absorbs residual gas in the tube. The plate must be heated to a very high temperature for the Zirconium coating to absorb gas. Current must be flowing between the cathode and plate for the plate to heat up. Operating in cut off state with filaments only will not heat the plate to the very high temperature required for the Zirconium coating to work. The heating of the plate to a very high temperature typically occurs when the plate, during normal transmitting, shows a "dull red glow". This is "normal" for these tubes and should NOT be considered a problem. I have seen inexperienced hams reduce drive when they see this "dull red flow" on the plate of their 3-500Z, thinking

there's a problem when there is no problem. That is the worse thing you can do for these tubes.

The plates of the 6146 and other low power receiving and transmitting tubes the plate should NEVER show any color!! Any signs of color showing on the plates of these low power receiving and transmitting tubes indicates a problem in the circuit. The circuit should be shut down, the problem found and fixed, before continued operation.

I now have a TS 530 project. There are several issues and I really have not dug in and started. I do notice a constant hiss or white noise in the Receive. It seems to receive, I don't believe it is what it should be The marker works fine with s meter indication.

If you move the band switch slightly to cut the band out and get a blank display with no receive, the hiss remains constant. It's like the white noise is on top of the received signal.

Thanks KB4MNG Brian

Jan:

Go back and read my response to your original recommendation. I was trying to ask you what was the objective of running the rig with heaters on? If not "cooking" or "gettering" the finals why would you recommend this procedure for a long stored KW hybrid? What are you trying to accomplish?

A much better approach would be:

1. Check to ensure has factory fuse installed.
2. Measure the resistance across the line cord power switch on = approx 2 ohms
3. Measure resistance from top of plate choke to chassis ground = approx 1.0 Meg
4. Then Dim Bulb start the rig. (I use 40w-60w-100w watt step start)

I was hoping you would come back and explain the running with heaters on procedure. I may be overlooking something. Yes you did not mention the word "getter" , but that is commonly the only reason people recommend to run long stored finals with heaters on. It wont work with 6146v finals as the getter design/process is not same as high powered RF amp tubes and the minute you turn the rig on you not only have heaters on your have 900vdc anode voltage applied .

The only way the getter element can perform its job is for current to flow in the tube causing the plate to heat to a high temperature. The filaments of these tubes are not coated with a gas absorbing substance and the filaments cannot heat the plate to the high temperature required for the getter element to do its job.

The tubes that have a coating on the filaments are tubes such as the 4CX250s, 4CX300, and 3CX1500. These tubes have a "warm up" period that must be followed before switching the tubes from cut off state to conduction state. Failure to follow this "warm up" period can result in arcing within the tube which can permanently damage the tube. The warm up period for these tubes is defined in the manufacturer's tube specification (see the tube manuals for these tubes).

There are some "diode" tubes such as the 866 and 3B28 for example, that are named "Mercury Vapor" rectifiers. These tubes have a "warm up" period that must be followed before HV is applied. The "warm up" period heats the inside of the tube by the filament, "vaporizing" the small amount of "Mercury" in the tube, hence the name "Mercury Vapor". When HV is applied the "vaporized Mercury" glows a "light blue". Failure to follow this warm up period can result in an ARC to occur in the tube which can lead to damaging the power transformer and other power supply components.

Tubes such as the 833, 4-400, 3-500Z, and 4-1000 for example, do not have a "getter element" but rather the plate has a "gray dusty" coating. The coating is "Zirconium", a substance that, when heated to a very high temperature, absorbs residual gas in the tube. The plate must be heated to a very high temperature for the Zirconium coating to absorb gas. Current must be flowing between the cathode and plate for the plate to heat up.

Operating in cut off state with filaments only will not heat the plate to the very high temperature required for the Zirconium coating to work. The heating of the plate to a very high temperature typically occurs when the plate, during normal transmitting, shows a "dull red glow". This is "normal" for these tubes and should NOT be considered a problem. I have seen inexperienced hams reduce drive when they see this "dull red flow" on the plate of their 3-500Z, thinking there's a problem when there is no problem. That is the worse thing you can do for these tubes.

The plates of the 6146 and other low power receiving and transmitting tubes the plate should NEVER show any color!! Any signs of color showing on the plates of these low power receiving and transmitting tubes indicates a problem in the circuit. The circuit should be shut down, the problem found and fixed, before continued operation.

Now that you all kindly solved my TS830 loading problem for me, here is another puzzle for you. I also have an ancient TS520. Everything appears to be working fine. However, in my first QSO, the rig exhibited a drifting problem-in both transmitting and receiving modes. Does that suggest a problem with the VFO? or something else?
Thanks,
Tim, WA3GPU

There are generally 3 or 4 schools of thought about what to do to power on a 30 year stored KW hybrid. All have to do with understanding what is the risk and what is your risk tolerance. What are the weakest elements? What is worse damage that could incur?

In my opinion weak links are:

1. The 800 filter caps, the 300 filter caps, the 210 filter caps. All could be dried out or at least oxide coatings are deteriorated. If they fault should blow the transformer primary fuse. This is stressful on the transformer and the rectifier diodes. Transformer is the high dollar item.

2. The finals could have off gassed or had in-leakage at seals and could arc over the minute they see 900vdc. (moment you turn the rig on)

So what are the options?

1. Just plug rig in. Turn on power. Watch and sniff and then turn on heaters and then attempt to load the rig. This school of thought is based on if something goes bang no big deal just identify and fix it.

2. Power on and bring up slowly with a Variac. This works but variac doesnt limit fault current and transformer is still at risk.

3. Power on and bring up with Dim Bulb method. SImilar to Variac accept if 1st low wattage bulb glows brite and does not dim down transformer is not hurt and you can then take voltage measurements to locate the fault.

4. Actually attempt to reform the electrolytic capacitors. This requires controlled voltage steps and measuring leakage current following a precise procedure.

I prefer some minimum testing and visual inspection followed by the Dim Bulb procedure. You can read all about it on the Antique Radio Forums.

But then you'd miss the joy of spending 3 hours or so with the XYL in a fabric store.
Has anyone ever got an accurate count of the "through hole solder repair" on the digital board for the 820S, as to how many?
I found 16 on only one board, none on the other.
I think I've asked 4 times now, anyone know?
On another 820S I'm getting "counting" on 28, 29 and 29.5 bands.
First places to look? I thought the 28.5 band was counting also (unstable digital display, running up and down), the 28.5 is not counting, it is stable.

Mark,
Here is my friend Dick's observation when he was on the other side of the QSO

I've been thinking about the drifting problem.

1. First it drifted one way,I think higher in frequency.
2. Initially, the drift was medium speed.
3. Then the drift speed increased.
4. Then the drift went one way, paused, and came back the other way.
5. The longer you tested, the faster the drift became.
6. Each time you hit the button to start another transmission, you were back on frequency and then began drifting again. Like it "rested" between transmissions.

When I was restoring the SP-600, I read an article about drifting suggesting that dust collected on the rotor and stator of the main tuning capacitor should be carefully cleaned out. Just a thought.

Bring the tubes anyway. We may learn something.

A friend of mine is giving me his old TS-820 that he bought as new and it has seen little use and hasn't been powered up for nearly 30 years! It has always been kept in his house and looks like it is brand-new! What precautions should I take before I power it up? I recall in reading somewhere, that a Variac (I have one) should be used slowly to re-form the caps. If so, just how would I go about this. Wish me luck, 73, Karl, KO8S

Usually the dirty rotor/stator is noticed when
the freq. shifts while tuning the main tuning
dial. That's not to say it can't cause drift and
is usually the first thing anyone should do
before doing anything more drastic.

If you go to the following link, you can see what
it takes to clean it. Actually I've found you
don't even need to remove the VFO from the case,
just tilt the radio onto it's left side, Take 1
screw out of the side plate of the vfo, then
spray the DeOxit in the rear. Then move the dial
from 0-500 a half dozen ore more times and it's
fixed. The article is for an 820, but it's the same for the 520.

http://www.n6wk.com/kenwood/TS-820-VFO--servicing.pdf

Now in some cases, like my TS-820S, I had drift
that continued even after the cleaning so I
installed a VFO stabilizer. It's now rock solid.
Installed it in my R-820 also.

You can also find the article on my web site.

Subject: Re: [TS-520_820_530_830] Gordon-n6wk - SK

It looks like there is plenty of space.

Even after we ad all of Gordon's stuff, he's still going to have over 2 TB left, so I'll be sending him a DVD with everything tomorrow. Not sure how long it will take him to upload it all, but I'll post something on here when everything is complete.

Mark, WB0IQK

At 02:40 PM 1/24/2014, Mark Gilger wrote:

I'm investigating putting all of Gordon's documents on my site. Depends if there is enough space. I should know shortly.

I had a lot of links that took people directly to his site for manuals, etc. that soon might not be able to do that.

http://wb4hfn.com/KENWOOD/KenwoodHomePage.htm

I suspect there will be enough room, just need some time to send files to administrator for posting. I'll have more on that later.

Mark, WB0IQK

At 01:22 PM 1/24/2014, David Yarbrough wrote:

I'm really sorry to hear this.Â Since I've had my TS-530SP Gordon's site has been my manual for the rig, in fact I don't think I'd ever even downloaded it but just kept opening the file off his site each time I needed it.

It's a shame to lose such a great resource and contributor to the community.

Hopefully his site will stay up but I know it can be trying for a family to deal with the all details that result from the loss of a loved one. Gordon's archive of Kenwood manuals is invaluable to the community.Â I don't have a good website to host such content on myself but I have made an archive of Gordon's files and am sharing it here:

https://docs.google.com/file/d/0B_nx4oLYGQ_KM3RjazV2UF9SRlU/

If others in the community would please download a copy to help preserve his work that would probably be good.Â The total zip file is about 905mb.

Thanks.

Topic: 47158 Message: 47192

Had and off the reflector question about why I did not mention re-capping the 30 year old stored rig before powering on as a viable option.

Well not many of us want to bring home a pristine cosmetic radio and have to recap it before we can turn it on. Average person is going to be real interested in firing this treasure up.

In practice installing a recap kit would be a more practical than reforming all of the electrolytics as the best way to reform would be to remove capacitors and reform individually on the bench where leakage current and temperature could be monitored during the process. Problem is that can take literally hours and different rules of thumb for what is acceptable leakage current. What caps would you chose to bench reform? If you are going to remove caps to reform them might as well replace them.

Alternative "reforming" method is to try to reform all caps simultaneously in place in their respective circuits by identifying the lowest WVDC rating and reforming the entire electrolytic population to that level and then moving up to the next WVDC level and reforming all to that voltage and repeat at each WVDC until you have worked your way up to the 450 to 500 wvdc population. You would do this with a Variac. Not a very practical thing to do and very time consuming taking literally hours up to and including overnight. No way to know if any individual cap in the population was not reformed to an acceptable leakage current.

So yes you could buy a recap kit and install it before powering up your 30 year old NOS KW Hybrid. I frankly did not think of it as I am not in the total recap business. If you opt for this there are some associated risks to be aware of:

1. Can pull molex connectors off the board or induce a latent fault that will manifest itself down the road. Probably less risk with rig that has not had lots of connector plug and unplug cycles on the boards. Common problem is a hair line crack at the pin pad to trace that isnt easily seen due to the solder mask and it can give you fits down the road. This is usually caused by side to side motion and rocking of the connector body during plug removal. Some of the factory soldering is very poor with the solder having never fully wetted to the pin.

2. Lift a solder pad. Need good de-soldering tool. I would hate to do this with spring loaded solder sucker or solder wick. A Hakko 808 or similar would be tool of choice for a project like this.

3. Installing replacement capacitors wrong polarity. Depending on which model KW rig there are several capacitors that are installed reverse polarity ie the positive terminal is to ground. If you are not paying attention to the removed orientation you could reinstall replacement cap incorrectly. In my experience the schematic and silk screening markings on the board are wrong. You can tell which is correct orientation if the capacitor is involved in a negative voltage circuit. Electrolytics anode and cathode plates cannot stand much more than 1 vdc reverse voltage. Look at Sprague or Cornell Dublier app notes on this topic.

So yes you can add total electrolytic re-cap to the list of things you could do before powering up your 30 year old NOS rig.

For me I would do some limited measurements and checks as noted, perform a visual inspection (dont want any insect nests), and start up using the Dim Bulb method. If you have a Variac and ammeter can do that as well, but you have no current limiting.

If you feel lucky go ahead and give it the smoke test! My guess is that this is probably the most common method.

Does anyone have contact with his family to see how they are coping?

How are they planning to dispose of his radio estate? It would be wonderful if they could get full value from his property.

If the family needs assistance perhaps a fund at one of the local banks could be set up for contributions in his name. Same with any charities. Often these touches mean a lot to widows and survivors--real world sentiment backed up by tangible resources to help the survivors of a much beloved friend and Elmer.

Just wondering. I often followed his advice to good end and I'm frankly tired of contributing only to political causes. This is an endeavor we could all support for this good friend and fellow ham.

Best regards
Larry, KS7J

> If you go to the following link, you can see what it takes to clean it. Actually I've found you don't even need to remove the VFO from the case, just tilt the radio onto it's left side, Take 1 screw out of the side plate of the vfo, then spray the DeOxit in the rear. Then move the dial from 0-500 a half dozen ore more times and it's fixed. The article is for an 820, but it's the same for the 520.

47197. VFO-230 For Sale

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-26 01:56:27 UTC
From: <ecoons@...>
Topic: 11863 Message: 47197

I have a very nice condition VFO-230 for sale with the connecting cable. This unit functions fine except it "misses" sometimes when tuning down meaning there is a position in the tuning knob rotation where it doesn't change the frequency. Tuning up doesn't seem to have the problem or at least not as much. I have been told that recapping the power supply will fix this but it hasn't been severe enough for me to bother doing it. Other then this the unit is in really good condition for it's age. I would give it an 8 out of 10. Pictures are available upon request. Price is $200 plus actual shpping. Please email me or call me at 518-566-0550.
Thanks, Eric W2EJC

Karl,

You should read Terry's recent response "today" about this very
topic. I cut and pasted it below:

"There are generally 3 or 4 schools of thought about what to do to power on a 30 year stored KW hybrid. All have to do with understanding what is the risk and what is your risk tolerance. What are the weakest elements? What is worse damage that could incur?

In my opinion weak links are:

1. The 800 filter caps, the 300 filter caps, the 210 filter caps. All could be dried out or at least oxide coatings are deteriorated. If they fault should blow the transformer primary fuse. This is stressful on the transformer and the rectifier diodes. Transformer is the high dollar item.

2. The finals could have off gassed or had in-leakage at seals and could arc over the minute they see 900vdc. (moment you turn the rig on)

So what are the options?

1. Just plug rig in. Turn on power. Watch and sniff and then turn on heaters and then attempt to load the rig. This school of thought is based on if something goes bang no big deal just identify and fix it.

2. Power on and bring up slowly with a Variac. This works but variac doesnt limit fault current and transformer is still at risk.

3. Power on and bring up with Dim Bulb method. SImilar to Variac accept if 1st low wattage bulb glows brite and does not dim down transformer is not hurt and you can then take voltage measurements to locate the fault.

4. Actually attempt to reform the electrolytic capacitors. This requires controlled voltage steps and measuring leakage current following a precise procedure.

I prefer some minimum testing and visual inspection followed by the Dim Bulb procedure. You can read all about it on the Antique Radio Forums.

Terry K9TW"

>A friend of mine is giving me his old TS-820 that he bought as new and it has seen little use and hasn't been powered up for nearly 30 years! It has always been kept in his house and looks like it is brand-new! What precautions should I take before I power it up? I recall in reading somewhere, that a Variac (I have one) should be used slowly to re-form the caps. If so, just how would I go about this. Wish me luck, 73, Karl, KO8S

I was always struck by what a gentleman Gordon was with everyone, I have asked a lot of pretty simple and sometimes ignorant questions and he was always patent and kind with this help.

I went to the site of his funeral home and read the comments. It was amazing how most of them were from Hams, most of whom had never met him but knew him from QSO's. He must have touched people all over the world based on the strentgh of his personality and kindness.

It is nice to see someone leave such a nice legacy of helpfulness and kindness.

47202. RE: TS-820, No transmit on CW or TUNE ..

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-26 15:42:35 UTC
From: <famtech@...>
Topic: 47070 Message: 47202

Problem solved !! Rig now works on CW and TUNE. Now, it has one last sticky issue to resolve and that is AGC recovery after transmit. When the transceiver is first turned on, receive gain is just fine. When placed in transmit in any mode and back to receive, gain drops way down. Powering-down the transceiver and back on recovers receive gain. Also, pulling the RF-1 connector and reinserting accomplishes the same bringing back nominal gain. Replacing Q2 on the RF board offered no remedy. Has anyone encountered this with their TS-820 rigs ??

Nothing worked on this rig when I got it, it had issues with every circuit board in it and except for this final problem, it's almost back to a completely functional and restored TS-820. Almost at the end of the tunnel.

Regards,

Jim L.

Topic: 46900 Message: 47205

Need tg o clarify, I don't suspect the driver because there are times when I get full ALC deflection, then it drops back to zero as if I'd let up on the switch. That leads me to suspect oscillation fails or flaky connection somewhere. I cleaned the bandswitch wafers pretty good and it made no difference. I'm looking for some advice on tracking it down with an RF probe to isolate where I'm losing the drive.

Topic: 47070 Message: 47206

I assume when the gain is down that the S-meter is reading up scale?

If so, the signal attenuation you are seeing is due to the AGC bus control voltage to the Gate 2 of the IF and RF gain controlled mosfets being lower than RF-1 set point level.

Have you tried cleaning the Aux relay contacts or swapping the Ant TR relay with the Aux relay?

The Aux relay switches your AGC and ALC reference voltage and if contacts dirty can see low AGC voltage when relay contacts switch from TX (ALC) and back to RX (AGC).

You need a very high Z VTVM like a HP-410C to accurately measure the AGC bus voltage.

You can also measure RF-1 to make sure it is stable at TX/RX transition, but I doubt it is moving.

Terry K9TW

Is it doing this just on 10 meters or on all bands?

If you have a single diode RF probe start by measure/monitoring the RF drive level at output of the TX Mixer at TP-4 on RF board. The Service Manual has the TX Level Diagrams on page 44 of the 3rd edition.

Should be 2 to 3 rms rf volts depending on the band.

I have decided to leave the price at $200 plus shipping and not raise it because the fix was so easy.

47210. Kenwood Hybrid Net Update (January 26, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-26 23:38:10 UTC
From: Mark Gilger
Topic: 47210 Message: 47210

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday 40 meter net had 20 stations checking in under good band conditions. There were 5 new stations checking in, KD8STE, K4JQL, WD8OSJ, WO3T, and DK8SUD. We had the following number of radios checking in.

6 running TS-520(x)
4 running TS-530(x)
2 running TS-820(x)
3 running TS-830S

I was running my TS-940s with an L4B amplifier.

Jimmy, WB3KNR ran the Sunday 20 meter net and had 22 stations checking in under good band conditions.. Out of those, there was:

6 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
5 running TS-830S

Jimmy was running his TS-520.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week

rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Topic: 46900 Message: 47224

This is just 10M band. There are times when I have full ALC deflection, then it drops to zero like snapping your finger. I figured I might have to chase it with a probe.
Here's what I see:

20M --> Drive at 3 o'clock --> ALC 80% full --> TP 4= -1.1VDC, no AC reading
15M --> Drive at 1 o'clock --> ALC 80% full --> TP4 = -2.0VDC, no AC
10M --> Drive at 1 o'clock --> ALC 0% --> TP4 = -0.2VDC, nop AC

Watched the meter as I adjusted the drive and it was climbing as the drive control hit the limit.

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Is it doing this just on 10 meters or on all bands?

If you have a single diode RF probe start by measure/monitoring the RF drive level at output of the TX Mixer at TP-4 on RF board. The Service Manual has the TX Level Diagrams on page 44 of the 3rd edition.

Should be 2 to 3 rms rf volts depending on the band.

Topic: 46900 Message: 47225

OK first of all take your readings with the SG switch off and the VFO at around 200. The ALC indication should peak at approx 1200 on properly aligned TS830. Start with the CAR level pot at 1200 (5) and if you dont get full scale ALC indication then run CAR pot full CW. If meter indication goes off scale just reduce CAR level to bring it back on scale.

You are seeing -DC volts at TP-4 due to orientation of your diode in your RF probe. You are reading peak AC drive voltage (at an RF rate) and the probe is converting it to DC and because of diode orientation you have to read it on the -dc mode of your VTVM or DMM. Only way to read AC RF drive at TP-4 is with an O-scope.

When you peak the ALC indication and then touch probe tip to TP-4 to take the RF drive voltage measurement your probe will likely detune the circuit and the ALC indication most likely will fall off. Peak the ALC indication before you touch or connect the RF probe to TP-4 and dont worry if it falls off when you contact the probe to take the reading. Your -2vdc reading is good but the -1vdc is a little low. Probably can be addressed with coil pack alignment. Of course 0.20vdc is bad.

Unfortunately this sounds like a bad bandswitch contact. Typically when you have no ALC indication or intermittent ALC indication on just one band it is often a bad Mixer tank coil bandswitch contact or a bad Drive tank coil contact or both. Losing the RF drive at TP-4 tells us that the Mixer tuned circuit isnt being seen at TP-4 on 10 meters. S1-4 switches in the proper Mixer tuned circuits at output of the TX Mixer Q6/Q7. It sounds like you have bad contacts at 10 meter position of S1-4.

If you had this problem on all bands then maybe a bad solder connection at the Driver tube socket or bad solder connections at the solder posts of VC-2 and VC-3 drive air variable capacitors.

There is one thing you can try to confirm if it is a bad contact and try only with the Screen Grid Switch OFF. DO NOT try this with SG switch on.

With CAR pot full CW, meter in ALC, Heaters on, VFO 200, CW mode, Flip to Send and gently move the bandswitch off of the 10 meters detent position on both sides as you watch the meter. Sometimes this wiping action can momentarily restore ALC indication. Once again make sure SG switch is off. Never want to do this with SG switch on as you would have rf circ current in the tank and you are not only changing the S1-4 contacts you are changing the S22 band switch contacts inside the PA cage and they are not made to break heavy RF current. They are there to select correct tank coil tap and correct amount of fixed padder caps. S22 should only be rotated when rig is in Rx mode if the SG switch is on.

If you get momentary ALC indication doing this test almost certain bad bandswitch contact. You could also have bad solder connections on the S1-4 vertical bandswitch board pins where mates with the coil pack board.

Before removing the RF board you could fold the Audio board over and remove metal access panel and look at soldering of the 10 pins for S1-4 deck.

Perhaps Dick W0NTA is following this thread and can offer other diagnostic tips. He is the bandswitch guru.

In my experience a well aligned TS830 with good Driver tube and good band switch contacts should get full scale ALC indication with the CAR level pot advanced no more than a maximum of 1000 to 1100 (position 4 or 5) with perhaps exception of 10 meter where you may have to open up to approx 1300 (position 6 or 7).

I tried your suggestion of rocking the bandswitch and there was no ALC on 28, when I hit 29M position I got full scale ALC. Beginning to think you're right about the switch contact. Can that be tested power off with ohmeter?

To ALL members,

I continue to see a number of members who are posting messages that do not contain an acceptable signature at the end of their messages. There is no excuse for a member not adhering to the group's message signature rule!!

An acceptable message signature is one of the following:

1. For licensed hams, first name and call sign
or
2. For non-licensed hams, first name only

SCREEN NAMES are NOT acceptable message signatures. Screen Names are acceptable ONLY as part of a member's e-mail address.

This is not a complicated or time consuming requirement. All it takes is for members to pay attention and ensure they have included an acceptable message signature at the end of their messages BEFORE the message is sent!

Well easy to get to the wiper of S1-4. Can clip a mini-grabber test lead in the square window cut in the hair pin loop. This is at approx 1130 position looking down at top edge of the red/brown switch wafer board. Only way I know to get to the bandswitch contact side is at the pin solder pad on the foil side of the board. This requires folding over AF board and removing metal access plate.

If you use a DMM to measure connect your meter test leads and any mini-grabber or other test leads you will use together and measure the resistance and record the value. Will need to subtract that from reading you get to get the contact resistance.

You are actually measuring two contacts in series....the wiper and the individual tuned circuit contact. Since the wiper contact is there for all bands you know it is OK.

Ohmmeter is not best way to do this as pushes no current but will give you an idea. A very good contact would be on the order of 50 to 100 milli-ohms. What you can do is measure resistance of contact where you have good ALC indication and use it for baseline reference.

Dave,

You can go to the "home page" of this group, under the picture of that wonderful Kenwood station, click on "conversations." Above that fine picture, enter your search criteria in the box that says "search conversations.".....say "TS-530S bias"...for example...and click on the box to the right that says "search groups." The more specific you are the better...so if you enter "bias" you are likely to get every msg/post with "bias' in it...maybe several hundred or more.

On a side note: please remember the group's identification policy...TNX

I just got word from Ken Kempski K4EAA that he is out of the replacement Omron LZN4 4PDT flat pack RL-1 Aux relay. I notice on HybridRestore site that Jim is also out of stock. I have done some internet search and cant find replacement source.

A Panasonic, Aromat, Matsushita NF4EB-12V is an exact replacement. Mouser, Newark, Allied, and Digikey no longer stock them.

Does anyone know of a source for these and preferably in the $25.00 range?

I have a customers TS-530 here that needs one.

Thanks
Terry K9TW

Topic: 47233 Message: 47233

I've been corresponding with the folks at International Crystals in Oklahoma. Nice folks, really sharp. Really up on their field, too, that's for certain.

I got the following request which, not having the crystals in the first place (the entire problem!), I cannot give them an answer.

> Do you have a sample crystal so we can test for load?

No, I do not have a sample crystal to return to test for load. I have two off-frequency crystals which do NOT work well at all. Those won't do.

Just for curiosity's sake, I tried to tune the rig up on the dummy load on the CB frequencies that the two 10-meter band-switch segments now provide instead. It didn't "play well," not at all....

I stopped really quickly, nothing seems to be harmed but I didn't like the sounds I heard for the half-second the key was down.

The rest of the email goes on:

> If not we can use the
> specifications ICM has on file but we cannot guarantee it. so worst case
> scenario without a sample you would purchase the crystals and if they are
> not on frequency return them with the readings for low, mid, and high trim
> to six digits past the decimal xx.xxxxxx and then purchase another set so we
> can get the load correct for your radio. We have found that over the years
> these radios have been in service the components age and then the load can
> be vastly different from radio to radio.

Sounds to me like it's going to cost me TWICE, at least, and that's only if I can provide lab-grade-precision correction information to them.

So, any advice?

Do I take a chance that they've got good data on file and that the radio will re-align correctly and the oscillators will work?

Or is there perchance a couple of crystals out there in someone's box-o-stuff which they'll part with, 36.395 and 36.995 MHz, I believe it was (according to reliable list members and the Kenwood parts spec. list) to put back in this 520SE?

Inquiring minds would rather like to know. What's my best option here? Oh, and money IS an object, I can't keep shoveling cash into this box for much longer. Luckily this seems to be (other than the re-alignment

chores which I will have to do myself) about the last of it before it's back in pretty good shape. I hope.

Wes,

If the leads are long enough on an original 10 meter crystal, ask Sarah Gore at International Crystals if you send a good crystals to use for load specs, will they ensure it's not damaged and it will be returned to you with the new crystals? You won't know until you ask her!

I have purchased crystals from International Crystal since 2007 for my Drake R4B, R4C, and T4XB, as well as crystals for my 1969 Regency scanners plus 2 old Johnson Messenger One and II converted to 10 meter AM, 11 meter transceivers. The crystals were within 100Hz of being on frequency.

I seem to remember I paid $22 per crystal plus a few dollars shipping for all of my crystals. I have been buying crystals from International Crystals since 2007 and never received a bad crystal!!!

Buy the crystals that ICM can make to the Kenwood spec they have. They will probably be better than any used crystals you can buy.

There is more than one crystal that determines the final frequency. Any one of them can be out of spec.

Sarah is who I'm dealing with at ICM. Problem. I don't HAVE 'good crystals' to send her. Lead length bedeviled.

Their quality is not the question. You already vouched for them, as did others, and that's plenty good for me.

I'm going to take the advice from Bob/K5MYJ, whose email arrived seconds after yours, and give them a whack as-is. I was pretty certain that I was going to have to go that route anyway, and I was fairly certain I could correct any small off-frequency behaviour down-stream of the HET-OSC board anyway. He confirmed that, in so many words, as well as giving a 100-Hz recommendation on their crystal-lapping accuracy to go along with your good words.

I suspect the price is a bit higher these days, but it shouldn't be too out of reach.

I'm about to order them. I'll mention both your good words regarding their service and products to Sarah.

Thanks again, guys.

Mark,

That's the same relay Ken, K4EAA, was selling. I have one of Ken's relays here as a spare, (NF4EB-12V), and I checked the data sheet from the link you provided, compared the pin layout and pin continuity and they are the same. Sorry, I won't sell my spare relay.

iiiC.cc has the same relay for $17.13 a piece but the minimum order is "20" which makes the total price $342.60 then there's shipping cost to consider.

Although onlinecomponents.com's price is rather high, $43.78 each, these "specialty parts" are becoming rather difficult to find. Pulling one from a parts radio is not advisable, quite often results in damaging the relay plus the relay itself most likely will have the same problem(s) your trying to eliminate.

I was killing time and trolled through a few website of our more well known members. One of them said that he got a great deal of good from a book entitled "Basic Radio Course" by John T. Frye. The book can be hard to find as it is long out of print but I did find a paperback on Amazon. I had to look several times The price was about $15.

"Basic Radio Course" is the best book on radios that I have ever read. Most texts or articles are highly technical and go into great detail and can lose you pretty fast.
For the first time this book taught me about how radios work and why in simple easy to understand language. I cannot recommend it enough to anyone that is not deeply immersed in the art of repair and understanding. It can be a bit hard to find but is well worth it.

Mark:

Yes this is the NF4EB-12V which is the correct relay which is a direct sub for the original Omron LZN4 relay. I have several of these in my stock I bought couple of years ago from Mouser. I want to keep them as spares for my personal rigs.

I have never seen another sub by any other manufacturer. I found these same ones you present here during my Google search, but I just hate to pay nearly $50.00 for one unless that is the state we find ourselves in now. I guess I wasnt clear on that?

Thanks for your efforts. Hopefully someone will have a source, but I am suspecting not. Those that have these know what they have. Ken hasnt given up on finding a source but wont help me with current need for customers rig. Dick Housden is also looking.

This is odd. I like Mike have ordered from Sarah more than once and never been asked this before. They have always provided a crystal based on the KW factory specs they have on file.

Perhaps you should send her a copy of the Het Osc circuit schematic so they can see it is a FET based oscillator.

I believe the crystals are 20pf, but not 100% certain.

I am not sure what part of the oscillator circuit is changing over time that would preclude using the original KW crystal specs that they have on file and of course no way for you to know how the oscillator components may have changed.

I guess she is saying if you have any good Het Osc xtal that is mixing with the TIF signal to produce the proper TX output signal from the TX Mixer then send it along and they will measure it and make one like it.

The Het Osc Xtals will have aged with time and that may be what she is really saying?

The 5mhz VFO mixes with the 3.395 Carrier Osc to produce the 8.8 mhz TIF signal. 8.8 mhz TIF mixes with Het Osc and the difference frequency is your actually transmit frequency.

There is no further mixing scheme after the TX Mixer to worry about.

Terry K9TW.

Kevin,

The book is difficult to find in either hard or soft copy at a reasonable price. However, there is an ebay seller who is selling the 1951 edition on CD under eBay ad #200692897318 for $8.99 plus $2.50 shipping. I purchased the CD to see what differences, if any, it had when compared to the 1961 hard copy edition I have. The only section that is missing in the CD's 1951 edition is the intro to transistors. Some of the pictures of test equipment are different but the text is the same.

I have been recommending this book on the group for a long time to anyone who want to learn electronics from the beginning.

It is mostly that there is ANOTHER thing wrong with it. I was -so-
close to being able to just USE the thing, and now -this-. Just
frustration, mostly. It never rains, but why won't it stop POURING?

> and I don't see that the other faults were necessarily down to the
> 27MHz conversion.

No, there likely isn't much correlation between the conversion and
several of the problems. But I do think that there MIGHT be some
connection with the noise figure problem I've been seeing, and the
really odd alignment which has been giving troubles. It's possible
there is some connection there. Being forced to be on CB didn't knock
that screw onto the high-voltage bus, that's for certain. CB is a pain,
but it's not THAT bad.... (Is it? ;-)

> There seems to be an attitude among certain elements of the community
> that if an HF set has been modified for CB, then even if it's
> adjusted back it will never be "pure" somehow, and that it will
> have been permanently damaged.

Now that's just silly. Again, it's just the "ONE MORE!" dropping out of
the blue and hitting me up-side the head. For a "perfect working order"
rig, this thing sure has cost me a lot of bench time, and more yet to come.

> If you dig back through the mailing list (I know, the web interface is
> hideous)

Worse. Nigh-unusable. The Yahooligans really need to do something about
this mess they've created in the name of "Moahr PROFITZES!"

I've taken to using the site: tag in a search engine and indexing it
from OTHER than their interface. And I do NOT use the web interface for
posting nor reading emails. THAT is what an email client program such
as Thunderbird is for....

then others have trod this path before. It starts with checking what
> crystals are actually fitted, and seeing what replacements you need to get.

Crystals I already figured. But are there OTHER things, such as coil or
capacitor changes that need to be done (un-done!) as well? Re-aligning
it, for certain. Hoping like the dickens that the buffoon who did this
didn't crack a coil core, or mangle anything important doing the dirty deed.

> As an aside, the VFO on my TS520 goes far enough "below 0" to get the
> top three or four channels of the UK CB allocation - but obviously doesn't do FM ;-)

No, but a DSP 'antenna analyzer' like the Micro908 (being repaired now (by the designer and engineer of the little beastie, at Midnight Designs, N2APB) apparently can be interfaced with these hybrids to provide AM, or so they keep telling me. That little box, hooked in correctly, can become a full PSK31 modem, with or without a computer, an electronic keyer, an automated Morse receiver and automated Morse transmitter, and a bunch of other things. Maybe even FM, though I don't see as that's really possible.

Sounds like too good to be possible, but I know at least some of that is being done, like the PSK31 and the keyboard Morse stuff. We;ll see about the rest.

I hope nothing too weird has been done, that I cannot find and un-do it. At last it was accomplished properly (as if there was any such thing!), and the rest of the rig seems to still be stable and in more or less working order now.

Wish me luck, Here goes Nuthin'!

Another good one is "Principles of Radio" by Keith Henney and Glen Richardson, published by John Wiley and Sons. I have the sixth edition, which was published in 1952.

Only has a couple of pages that detail transistors- Looks like there are several copies available on Amazon for cheap.

Did you try to measure contact string resistance and watch it as you rocked the band switch to make sure you were on the 10 meter mixer tuned circuits? If contact is bad which is the more common problem then touching up the solder at board pins wont help.

Actually the contacts themselves are seldom the problem accept for those that have been damaged by people using right angle cleaning tools that bend or spread them. fortunately hard for them to get to the back side of the contact. The most common source of the high resistance and intermittent rf drive problems is the rivet to pc trace contact area. It has lost its pressure and has oxidized.

Only way to fix this is to remove board and clean the oxide off with caustic cleaner, dremel tool, X-acto knife etc and then to solder the rivet to the trace or use the silver pen method. I prefer to solder but not go crazy.

In this path you have essentially 4 places for IR drop. At the wiper contact, at the tank circuit contact, at the rivet to pc trace interface, and at the board pin solder. All four in series and in my experience the problem child is the rivet to pc trace.

When you get done with repair need to measure the resistance of that series string to make sure you have really affected a repair. You cannot press on the contacts to restore low resistance. You might be able to give a very slight twist, but I would not mess with either contact until I fixed the rivet to trace interface and then measure the resistance. You can do that with DMM or ESR bridge or dc bench supply and apply 6vdc @ 1 amp and read millivolt drop across the string.

Kevin,
Thanks for the info on the CD version on eBay.
I just bought one and suspect you sold a few for that guy.
I saw a hard copy sold on eBay cheap yesterday too, and I do hope it went
to a forum member.
Terry K92W had just told me about this book about a week ago but I was busy
working a few 12 hr shifts in a row and didn't search for one at the timw,
so missed on the cheaper hard copies, but I think the PDF on the CD will
serve me well since I can send it to my kindlefire and read it on there
too, I am glad it is the early version that is more focused on tube radios.

Tom,

I am the one, not Kevin, who posted the information about John T. Fryes 1951 edition of his "Basic Radio Course" being sold on a CD by an eBay seller under eBay ad #200692897318.

I have not made available nor have I sold any John T. Frye "Basic Radio Course" book on CDs, on eBay or any other online auction website or even privately.

I simply bought the CD from the eBay seller to compare it against the 1961 hard copy edition I have to see what differences, if any, the 1951 CD edition has. As I said, the only difference I can see is the CD's 1951 edition does not have the intro to transistors and some of the test equipment pictures are different. Other than that the book's text is the same.

The Basic Radio Course by John T. Frye is becoming very difficult to find. I found my hard cover copy, 1961 edition, at a used book store for $2.00. Local libraries may have it but one would have to check with their local library for the availability of the book.

Hiya fellas,

Last night I replaced my 530's stock SSB filter with an 8-pole 2.8 KHz gem from INRAD. It sounds terrific on receive and transmit audio reports are flattering.

Anyone else made the swap and is a re-alignment indicated?

Thanks and 73,

Craig

It was actually Mike W5RKL that came up with the idea about the CD.
By way of explanation 40 years ago I studied Electronics at the college level. I was capable of designing basic audio amplifiers etc.to a spec. However I learned to do it using math. It was remarkable to me that the entire thing breaks down to math and then you find components to fit the math. This was fine and well but only gave me a narrow focus and no practical experience. Over the years the basic principles have stuck with me but little else.

I have memorized and learned enough to pass my General but that only scratches the surface when it comes to staring at a radio with problems. I find most books are way too detail oriented to give me a good grasp of what I am looking at. For me if I understand the basic building blocks from a practixal point of view the rest comes with time.

I restore old cars and when I get a new one to work on I buy all of the different repair manuals that I can find. Each is written from a particular point of view. I always fine something in one that I can't find in another or it clarifies something that may not be clear. I think radio books are the same way.

This is not the worlds best radio book, but it is a great primer at least for me. It was Mikes page that first pointed me at it and I have really enjoyed it. I will not pick up the other book mentioned here.

Craig

Anytime you change filters it is good idea to bring the Carrier Osc to the filter. You cant do anything about the filter response curve. All you can do is decide where you want to insert the carrier oscillator.

Some call it adjusting the carrier "set point". The Service manual has you adjust the SSB transmit frequency response using AF generator and Wattmeter and injecting low millivolt level audio into mic line and adjusting the LSB and USB carrier oscillator trimmer caps for equal 3dB roll-off at 300hz and 2700hz.

Some fellows do it by ear. Others do it using the Marker and S-meter zero beat method (described in Survival guide) and other uses Spectrum Analyzer including Audio Spectrum Analyzer software like Spectro-gram and a noise bridge.

I normally do it with AF sig gen and wattmeter and then check it with Spectro-gram and run a copy of the as left response for the customer. I explain to them how to adjust the trimmers if they do not like the response where I leave it as it is a user preference adjustment. Some like more bass and others more treble presence for communications audio especially if running barefoot and chasing DX. How you adjust for Rx is how it will sound in Tx and vice versa.

Craig

I forgot to mention that if you use the audio or function generator method you need a way to make sure the millivolt level does not change as you adjust the frequency from 300 to 2700 hz. More sophisticated generators have an ALC circuit and the output level stays constant as you adjust the output frequency. Absent that you need a way to measure 5 to 10 millivolts AF level so you can check and adjust it as you move frequency.

I dont have a lab grade function generator, but I do have a good HP true RMS AF voltmeter so I can make sure my low level audio is same.

The average ham is probably better served using the Marker / S-meter zero beat method or audio spectrum analyzer soft ware.

Good thing is it is pretty hard to get in trouble. When done just turn AF gain up and go to clear channel and flip back and forth between LSB and USB to see if background hiss is close to same tone. Other thing you can do is also listen to self on another receiver.

If you are happy with how the Inrad Rx sounds now and the off air Tx reports you are getting just leave Car Osc set as they are now.

Terry K9TW

Greetings from "bloody hot" South Australia

recently purchased a 520 which I am having a small problem with and need to discount "operator error" as the probable cause.

In "tune" mode I can not get any reading at all on the meter to dip the plate, however when I switch to full power [CW] I can then dip the plate and get rated power out.

I am not familiar with the Kenwoods, so appreciate any tips.

Wes
As we have talked before I thought I would keep you up to date on the Kenwood Replacement Sprocket project. I now have completed a small production run of both large and small sprockets completed. I am very satisfied with the product and will send my first products to Terry for a review. When he gives me a thumbs up I'l share with the others on the Kenwood Net what I have available. I have no intention of running a business this is still a hobby to me. At this time I have only shared with Terry and you my success and progress. At this time I still have one little bug to work our and that is in the first run the center hole is about 0.0005 inch too small. It requires a little too much push to slide on to the original Kenwood shaft to suit me. So I have ordered a reamer a little larger to hopefully solve that problem. That problem hopefully will be solved by the end of the week and the finished parts will be off to Terry for review. The material I used has a Tensile Strength of 5,000 psi. They are tough, you can dance on them if your agile and maybe hang on to a walker. HAHA. So have a look at the WEB site and hold off sharing information for a few weeks until I have everything proven out and reviewed. Only Terry knows about the WEB site. See http://www.nr6c.com/sprocket.htm http://www.nr6c.com/sprocket.htm

I.e. for your information the advances in Rapid Prototyping or 3D printing are huge. They are now printing composite materials as well as metal. Can you imagine a 3D printed metal die? ABS materials can now be selected in all colors in the color pallet and are being used for breast plates, Armor and a wide verity of movie costumes. Amazing the advances. The last Olympic winning Bob Sled was 3D printed. So, your comments about 3-D printing not having lasting power..... Well not as we know it today, the super materials they are printing today are awesome even tho we don't need them for our Kenwoods. HAHA

Greg,

The problem is probably caused by resistors R5 and/or R6 (I'm recalling the part IDs from memory so check them on the schematic), both 56K 1/2 watt, on the HV board. These two resistors form a voltage divider network that reduces the final tube screen voltage in TUNE mode. They are not involved when in full power CW mode.

Greg,

Wish I could send ya a pint...but:

This sound like the problem that plagues many of the Kenwood hybrids.

Check the value of Resistors 5 & 6 (56K each) on the rectifier board (X43-1110-00).

I'm pretty sure that you will find them way out of value...or one open

It's better to just buy the new crystals from ICM. Any crystals from a parted out rig are questionable. They are 50+ years old.

We are discussing Het Osc crystals. The TS530 is a PLL rig no similarity to TS520, TS520S or TS520SE rigs. The TS530 uses a VCO signal as the LO for the Transmit Mixer.

These relays seemed to dry up very quickly about a year ago. Digikey posted on their site a limited number available and they were quickly sold. Online components had about 800 on hand at $7. In about a week the price quickly shot up. I saw these relays on ebay about 2 months ago at around $30. At that time, I told several looking for them and they bought them up. The only thing I can suggest is keep a check with ebay.

Is the 100 ohm resistor mod to the relay a good mod? seems like they are subject to excessive current they are not designed for and failing.

Terry, have you found these relays failing in the rigs you have worked on?

Thanks kb4mng

Terry,
This advice from you has worked out great. The 530's Q1 appeared to be working and L41 appeared to be bad (from injecting signal at TP1 & S1-2 solder tab. Now (maybe from static discharge from poking around) Q1 is not working. So, I'm going to remove & troubleshoot L41 (and rewind it if bad) and will want to replace Q1. What are you guys using as a Q1 replacement? An NTE222? I see MCM has them for about $14.
Jan N8CBX
(Thanks again Terry for the advice, its helped me tremendously)

Bob

If that were true then every TS520 in existence and on the air today would be experiencing problems with Het Osc and Transmit Mixer issues. I am not aware of any Het Osc issues that people are starting to see with their TS520s??

99% of time no problem with using a Het Osc crystal pulled from a TS520 board or buy a board from Bob Mansker and swap the boards. Done all the time.

I have couple of complete sets of hanging boards which have allowed me to keep customer and my own TS520 on the air.

If ICM can no longer provide TS520 het osc crystals then I would not hesitate to pull one from a parts board or swap the board.

Bob Mansker is reducing his overstock of TS520 boards at this time. If Wes plans to keep his TS520 for any amount of time he might want to consider checking with Bob to see if he has a board and what he gets for one. I have had very good success with anything Bob sells.

Brian:

These relays control functions like Rx and Tx bias and S-meter and ALC metering. I am not convinced that switching a capacitive load is the issue especially since not all 4 contacts see reactive load or inrush current or arc discharge. In fact some arc discharge is good as it breaks film build up. Just dont want high inrush current to weld the contacts and dont want projections to build up to bridge the contact gap. These relays see a lot of operations and contacts are very small. Lets just say adding RC arc snubber cant hurt.

People have been doing the relay "TAP" test for some years now to diagnose cause of intermittent functions and some remove the plastic cover and attempt to clean the contacts. This is difficult in place and the contact leafs are very delicate. I have never found this to be a long lived fix. I have attempted to burnish contacts with diamond burnishing tool without much life extension.

I was recommending that customers replace the relay as a matter of routine when the relays subs were readily available and could be had for $10 to $15 from Mouser and Newark and Allied. Now I only replace one when troubleshooting indicates the relay is the source of the operational issue. I have replaced the relay in both of my TS830s about 3 years ago now with the Panasonic/Aromat units.

That is where I am at today with a customers TS530 rig. It has two sets of contacts that measure close to 1 ohm resistance and should be closer to 50 to 100 milli-ohms. I have recommended replacement to the customer while I have rig here for repair and alignment and thanks to the generosity of our fearless leader Joe I was able to install one of my personal spares and Joe is selling me a NOS relay to replace my stock.

I would not lay awake at night worrying about it. It may be as I think Mike stated the case that we will soon be faced with paying $50 for replacement as only option to keep the rigs on the air. Lots of rigs and test gear out there with unobtainium parts. We sometimes forget that the KW Hybrid is well past its design and economic design life.

If you plan on keeping a TS530 or TS830 for any extended period of time might not be a bad idea to get hands on one or two of the NOS subs and put them back for future need.

In about a week the price quickly shot up. I saw these relays on ebay about 2 months ago at around $30. At that time, I told several looking for them and they bought them up. The only thing I can suggest is keep a check with ebay.

Is the 100 ohm resistor mod to the relay a good mod? seems like they are subject to excessive current they are not designed for and failing.

Terry, have you found these relays failing in the rigs you have worked on?

Thanks kb4mng

Jan:

I doubt you hurt the Q1 RF Amp. It may well be bad but probably occurred at same time L41 was damaged.

I would check with Scotts Electronic Parts. He sells parts for crystal radios and was selling original 3N211 and 40673 mosfets. Both work just fine and run around $6 to $9 dollars. Yes a NTE222 or NTE 454 will also work.

When you get L41 rewound I can give you my bench test procedure to check it before you put it back in the rig if you are interested. Just need good RF sig gen and RF millivolt meter or O-scope to drive it with. It test above 1.8mhz out of circuit. With it removed also good time to drive the BCB high pass filter and make sure it isnt hurt. I can give you simple procedure to look at its cutoff frequency.

You should also check protection diode D2 while you are at it. It is there to protect the Q1 RF amp from the rigs own internal transmit RF. It does that by being biased on when you have Driver tube current and shunting any RF that appears at Q1 Gate 1 to ground thru C44 and the diode. Some folks think it is for ESD protection and it is not. Only time it is forward biased is when you have IR drop across cathode resistor R35. A good way to test is to apply bench supply or battery across R35 and see if D2 pulls RX signal down. If you have board out to replace L41 can just lift one end of D2 and test it.

Oh yea, I see now it was you, Kevin, that first mentioned the book and Mike posted the info on the CD.
I know what you mean about the basics, I would not get all the math either and have tried to read more then one radio book where most of it goes over my head and I don't really learn anything of practical value. I also just ordered "Principles of radio" that Terry, recommended to me too. Glad to have experienced elmers point me in the right direction.

Terry,
Awesome, thanks.
I have L41 removed and the winding resistance (easily done) is
0.965/0.245 ohms, no shorts. I have both & good RF sig gen & O-scope and
I can bench test L41 with your proceedure, thanks.
I'll check the other components tonight after dinner.

Looks like you are getting on well there. $14 US for an NTE222 seems
pretty expensive.
I got some equivalents from our local Auckland VHF group trading table
for the equivalent of $0.80 each recently.

From memory my TS 820s relay also failed. When I came to fix it I seem to remember that the pin outs on the Kenwood relay are not standard. It meant quite a bit of careful rewiring, but worked fine afterwards. Can you get the (apparently) special relays in the US?

Jan:

Dc resistance isnt a very good check. One shorted turn and it is no good. OK to start there. Here are specs:

1. Pri 6 turns #42
2. Sec 26 turns # 42
3. Pri ohms = 0.25 ohms
4. Sec ohms = 1.00 ohms
5. Pri inductance = 0.85 uhy
6. Sec inductance = 15.5 uhy

Note: Inductance read with digital LCR bridge with iron core flush with top of shield can

To test on bench excite the primary with 10mhz to 12mhz RF signal. Use as low a level as possible to avoid saturation. Measure rf voltage across secondary with RF millivolt meter or O-scope.

With 5mv @10 mhz injected into primary should see approx 40 mv output across secondary

With 50 mv @10 mhz injected into primary should see approx 450 to 500 mv output across secondary.

This is with the output voltage peaked with core approx 1 turn outside top of shield can.

Turns ratio = 26/6 = 4.33 to 1
Ohms ratio = 1.0/0.25 = 4.0 to 1
Uhy ratio = 15.5/.85 = 18.24/1 square root = 4.27 to 1

It is a nominal 4:1 step-up transformer, but wont see that in circuit once secondary is terminated.

If you look at the RX Level Diagram in service manual you will see 0dB (-113dBm) at primary and 10dB (-103dBm) at secondary.This is 0.50uv at primary and 1.58uv at secondary. 1.58/0.50 = 3.16/1 voltage step-up in circuit. 10 dB gain across L41 = 3.16 to 1 voltage gain in circuit.

Make sure you wind both the primary and secondary counter clockwise viewed from the top of the spindle.

Mark:

I dont know what kind of AF gen you have but point I am trying to make is that if it is typical of most of the old Heath style generators then wont have a calibrated output level and no ALC circuit and if you have no way to accurately measure AF voltages at millivolt level you can be kidding yourself. Easy enough to use Freq counter to see what actual output frequency is as most hams have a counter.

Easy enough with one of these old AF generators to set your mic gain to say 1200 then set sig gen for 1200 hz and key the rig and adjust sig gen output level for 50 watts on the external wattmeter. So far so good. You have no idea if you are injecting 5mv or 7mv or 10 mv, but at this point you dont really need to know. However you do need to know that it does not change for next steps. If you dont know what it is pretty hard to tell if it has changed.

Now you swing the AF sig gen down to 300 hz and see 25 watts or you swing it up to 2700 hz and see 25 watts and you say man everything is cool. It could be and then it could not be. You dont really know as you dont know if the 25 watts is due to the fact that you are seeing the 3dB roll off point of the filter response curve or the millivolt output level of the AF sig gen has fallen off from where it was at 1200 hz (not an uncommon problem).

So using Spectro-gram or similar software is far superior to using a low budget AF sig gen. Ideally need a noise bridge with it, but can be done without one by just using receiver back ground noise.

Look at the sample response curve I placed in Files under Repair folder. It is fun and simple and accurate way to set Carrier point. You can find several articles on web on how to use Spectro-gram to adjust Elecraft carrier oscillators.

I provide each customer with hard copy of as left LSB and USB curves.

On Wednesday, January 29, 2014 5:53 AM, "wagstw46@..." <wagstw46@...> wrote:

Did you try to measure contact string resistance and watch it as you rocked the band switch to make sure you were on the 10 meter mixer tuned circuits? If contact is bad which is the more common problem then touching up the solder at board pins wont help.

Actually the contacts themselves are seldom the problem accept for those that have been damaged by people using right angle cleaning tools that bend or spread them. fortunately hard for them to get to the back side of the contact. The most common source of the high resistance and intermittent rf drive problems is the rivet to pc trace contact area. It has lost its pressure and has oxidized.

Only way to fix this is to remove board and clean the oxide off with caustic cleaner, dremel tool, X-acto knife etc and then to solder the rivet to the trace or use the silver pen method. I prefer to solder but not go crazy.

In this path you have essentially 4 places for IR drop. At the wiper contact, at the tank circuit contact, at the rivet to pc trace interface, and at the board pin solder. All four in series and in my experience the problem child is the rivet to pc trace.

When you get done with repair need to measure the resistance of that series string to make sure you have really affected a repair. You cannot press on the contacts to restore low resistance. You might be able to give a very slight twist, but I would not mess with either contact until I fixed the rivet to trace interface and then measure the resistance. You can do that with DMM or ESR bridge or dc bench supply and apply 6vdc @ 1 amp and read millivolt drop across the string.

Go to Ron WB4HFN website and look under the Kenwood Net Home Page and look under Articles and you will see Dick Housdens excellent procedure and close up pictures of the vertical band switch boards.

You can also go to Ken K4EAA site and see his pictures. Ken uses the silver pen method and Dick uses the solder method. I have done both and only do solder now.

Some folks apply the solder and a small jumper wire back at the contact hair pin turn window to keep the heat away from the contact for fear of losing spring temper. I have done it both ways and if you have very good clean bright metal at the rivet (I also apply a drop of liquid rosin flux) you can get in and out pretty quickly. It doesnt take very much solder to bond the rivet, contact material, and pc trace together electrically.

Dave,

The rivet(s) in question are on all the band switch wafer boards. They are small. They hold the
springy fingers to the phenolic band switch circuit board. Some boards may have up to 12 ..some maybe only 4...it depends on the wafers position and function. Sometimes there may be some corrosion..lack of tightness...etc that causes poor/no contact for a particular finger or fingers.

The Heathkit AG-9, IG-72, IG-1, and IG-18 all have calibrated outputs.

And the Heathkit AV-3, IM-21, IM-38 , IM-5238 AC VTVMs can be used with other signal generators that do not have calibrated outputs.

http://www.nostalgickitscentral.com/heath/products/heathkit_test.html

The Heathkit AC VTVMs are a low cost alternate to the HP 400 series AC VTVMs.

Has anyone tried using the solder paste that is made for surface-mount devices, and the liquid flux pens for the de-oxidation?

(That is what flux is mostly for, keeping out oxygen and removing oxide compounds before the soldering temperature is reached, so that the parts to be bonded will be at their cleanest and least-oxidized when the solder flows.)

I should thing that a pin-point heat gun nozzle, such as comes with a Weller PyroPen butane soldering torch, and the paste solder with the non-rosin liquid flux might make this a much easier job with a better chance of a good bond.

I do not think my band switch is in need of this treatment at the moment, not yet at any rate. But unless someone has tried it and knows there is no good to come of that sort of soldering technique, that would be the first thing I would try. I think I would also use the wire from rivet to pad addition as well, seeing as that makes it certain to be a good contact all the way to the edge of the wafer.

Do you all ever use solder-wick de-soldering aid as a source for wire to repair traces? A military soldering school instructor, friend of mine down at Goodfellow Air Force Patch in S'nAngelo, TX taught me that back in 1983 or 1984. I sat through his soldering repair class, the school ran 24 hours a day and nobody cared if I came in and sat through the classes in my off time, between rousting students back and forth to their classes. (I was temporarily assigned duty as a military training instructor; dress-right, dress, forward, march, aiguillette on my epaulets and funny hat and all.

I even took the final exam in soldering, passed it, too, The test consisted of repairing a computer peripheral card, and in '83, a parallel printer card was about 14 inches long and had hundreds of components, on both sides.

The printer card was used to print a page, the computer was turned off and the card removed, and then the instructor (my buddy from an earlier deployment, we were both in West Berlin) snapped it in half across the edge of a bench. IC chip shrapnel every-which-way, and I had two hours to print a page using it, timer starts NOW.

I made it, with a few minutes to spare. Wish I could do that well now, with these mangled-up mitts, but then it was rather a lot of fun, mostly.

Anyway, rag-chew over, to repair the traces on the board once the epoxy had physically stuck the two halves back together, we used either 28-ga. or finer wire, of for the larger width pads and runs, sections of solder-wick pulled tight and flattened into a narrow ribbon. They took solder instantly, were as conductive as all get-out of course, and mechanically easier to epoxy down on the board, being flat to begin with.

So solder-wick, paste SMD solder, and non-rosin pen flux. Comments, any who have knowledge of whether this will work on rivet repairs?? Sounds good in theory but a lot of things that sound good on paper stink in practice.

If you know otherwise please save me from the folly of trying it, thanks.

A quick aside, the ICM price for HET-OSC crystals for a 520 series (mine is an SE) is $23,25 with a three-week turn-around time from ordering, and that doesn't include postage to get them here. I am calling them tomorrow to seal the deal and get them started lapping my two rocks. Since they're so small, an envelope and US Postal Service should be just fine for the shipping, probably $2 or $3 dollars, shouldn't be more for a small padded envelope from Oklahoma to Illinois.

Bob:

I did not say it could not be done with a Heath AF gen or similar quality unit. I simply said you have to be able to measure 5 mv to 10 mv accurately off the panel meter at 1200 to 1500 hz and make sure it stays at at that level at 300 hz and 2700hz. If you and Mark can do that with your Heath gear then great. You have what you need to perform the Service manual method to bring the carrier oscillators to the IF xtal filters. .

I still have a Heath IM-18 on my bench and use it from time to time. Nothing wrong with modest test gear. Heath made it possible for me and countless others to be able to experiment and work on our radios.

As with all test equipment you have to be aware of its limitations and how to work around that. Doesnt take you long to understand what those limitations are and having accurate step attenuators has always been weak link with all the low end signal generators.

I remember first time I was aligning boatanchor receiver with my IG-102 and got done and was pretty happy with myself. Man this baby has pretty good sensitivity. Then I removed the test lead off the SO-239 and realized I could still hear the signal in the rigs speaker just about as loud as I did with it connected. I had just kidded myself. I had no idea where the MDS was at and frankly back then had no clue what a uv or dBm was. Still had loads of fun.

So I still contend it is so much easier to use a lap top and Spectrogram or one of the many audio spectrum analyzer softwares. I am not a computer guy and if I can do it anyone can. Most new KW hybrid owners are far more likely to have a computer and can down load free versions of the software. Easier and faster and cheaper to do than for them to buy Heath AF gen and Heath AC VTVM and refurb them especially where 5mv to 10mv is at on one of these units.

I am simply making people aware of the options available to them to adjust the Carrier Oscillators in their KW Hybrids. I have on numerous times listed about 5 ways to do this. I told Craig if he is happy with the off air Tx reports and how the Rx sounds he could do nothing. Some people set them with a freq counter to the frequency listed in the service manual and call it done. Others use the Marker/S-meter zerobeat method.

Much of what I say on here is not for experienced people like you and Mark. I am focusing on the new folks and new KW hybrid owners. I try to give options that I know will work. I seldom say there is only one way to do anything. Of course some methods are better than others.

Terry K9TW

I noticed a couple things. This reminds me of my time at Harris RF, the company that builds Military radios. I also noticed mostly women building the radios and the only one wearing safety glasses was the person soldering manually but they had no side shields, both of these required on any manufacturing floor in the US. You are right though, works for me too, I have yet to see a price. By the way, the link works just fine. Brad KB2CHY

Want to publicly thank our owner Joe who has sold me a NOS RL-1 aux relay from his personal stock. I can now install this in customers rig and not have to resort to installing a "good" Omron LZN4 pull.

Thanks to those who also wrote off the reflector and sent me numerous links that they found.

I probably phrased my question wrong. I had done similar Google searches and was aware of most of these sites. What I really wanted was two things. 1. Anyone have a spare that they were willing to sell and 2., Do you have a supplier other than Ken or Jim where you routinely buy these relays at or near $25 price or better in single lot quantity. .

I have talked to several others who regularly work on KW hybrids and none have a source other than Ken K4EAA. .

Dick W0NTA and Dave VK5PDL are presently both looking. Both routinely work on TS530s and TS830s. Of course we can be sure that Ken K4EAA continues to search as well. Hopefully someone will come up with a reliable source around $25.00.

So thanks to all and especially to Joe who helped me out with my current commitment to a customer.

If the caps are going bad in the TS 530 what indication will you have on receive. I have a predominate hiss in the rx audio. No matter what you do, change bands, modes, antenna unplugged, its there. The rx and s meter are fine, just the hiss. The his is controlled by the volume.

It's going to hiss at least a bit. Is this distinct from the "RF noise" hiss?

I have hardly ever (maybe half a dozen in 25 years or so) seen an electrolytic capacitor fail, that wasn't in a cheap shitty switched-mode power supply. If any electrolytic is going to fail in one of the Trio hybrids, it will be a PSU capacitor and you'll know it's happened ;-)

From: <wagstw46@...>
Topic: 47286 Message: 47291

Is this something new?

Normally when you disconnect your antenna or switch to dummy load you should hear a nice even constant hiss with the RF gain set to max and AF gain at comfortable listening level. Should be no S-meter indication. This is the internal noise produced by the receiver most of which is mixer noise.

Then when you connect your antenna should hear a significant increase in this noise and see S meter indication.

Is this what you are seeing?

Do you have a VTVM with a dB scale on it? If so you can measure your receiver noise gain. Very easy test as follows:

1. Tune receiver on 20 meters to a clear frequency.
2. Switch to dummy load or remove the antenna from the rig
3. Connect your VTVM set to AC mode across the speaker (can do this on external speaker jack). Some folks connect a 8 ohm dummy load resistor across the external speaker and connect VTVM across it so they dont rattle the speaker too much.
4. Set RF gain full CW and increase AF gain for -10dB reading on the VTVM. It may move around a little so just average the swings if it does.
5. Switch back to the antenna and read the dB level. Should read approx +3 to +4 dB.
6. If you have a beam rotate it to see biggest effect as direction will make a difference.

You have just measured the Noise Floor or MDS of your receiver. If you get close to these results nothing wrong with your receiver.

Topic: 47286 Message: 47292

I forgot to mention and it may be obvious but do not move the AF gain control after you set it to -10dB at speaker with no antenna. If you are doing this measurement across the speaker instead of a dummy load resistor the volume might startle you when you flip back to the antenna to record the change in dB indication. Must leave AF gain pot at same place for accurate results.

Neil,

I know of no supplier that would just sell you the clip, except someone in this group that may have something for you. I have also had a broken mic clip...on a spare MC-50. I washed it in detergent and water...let dry...used some isopropyl alcohol to again clean the surfaces, and used a QUALITY "super glue" to "fix" it. It is still serving today.
I do not know what you have available on the other side of the pond...but "Gorilla Glue" is what I used. It is available at many "home improvement stores" here in the colonies...hihi

Cheers,

Terry & group,
Thank you for the insight in testing L41, I did a bench test today and the secondary voltage looks low. I captured a screen image from my scope and posted it here for everyone to see.
http://janswerks.com/n8cbx/kenwood/L41_signals.jpg
(I did peak up the output w/slug, and injected 10mhz at 20mv, to see the primary sig. clearly on the scope. I didn't see any saturation)
I ordered a spool of #42 ga magnet wire today, so early next week I'll be re-winding L41. I forgot to mention that D2 measured OK, and I bench tested the 8.830 wave trap and did a slight adjustment but that whole input circuit (up to L41) looks good.
Question - If I bench test the RF board, would I need to apply just 12VDC to the board?

Terry & group,

Terry, tnx fer ur nice comments. I was told early on...that this is what "hams" do. I try and carry it forward. You have also given lots of your time and experience at NO CHARGE to this group. Between you, Mike-w5rkl, and of course Gordon-n6wk(sk) and, others, I have learned more about diagnostics and electronics in general, Kenwood hybrids specifically, in the few years I have been a group member and, now Co-owner, than in my previous 30+ or so years..of just being an "operator."

So, that being said, let's continue to help each other...with our knowledge and expertise as
it's not going to get any better, or easier, trying to find/obtain parts...as long as Bob-ke5ftf is around we're doing good! We've got some great pieces of radio equipment here!

Jan:

Well this is lower than the 8 to 10 x voltage gain should see at 10 mhz. Did you try it at 1.9mhz as well? 3.16 x voltage gain is in circuit.

I have never seen a bad L3 or L4 wave trap as result of ESD or accidental transmit. More common is bad BCB high pass filter. L1 choke can short and input signal at Ant will be shunted from C1 thru L1 to ground. Need to sweep BCB with RF sig gen. Can connect sig gen at Ant and connect RF millivolt meter or O-scope at the solder pad where you removed L41 primary hot end of winding and inject starting with 2 mhz and sweep down in frequency and watch output voltage as you go down in freq. Will see a voltage peak at around 1.6mhz at knee of response curve and then voltage should fall off sharply as you go down in frequency.

You can look at the circuit and see you will need more than 12vdc. Depends on what you want to do. If you want to just see if you have proper step-up thru L41 and proper gain at Q1 Drain need one set of conditions. If you want to see if the board can produce RIF output and jumper that to the IF board you will need to inject VCO LO signal. Ideally you also need 9vdc to control the receiver attenuator at input to buffer amp Q2. Bias voltage is used to control D3 which switches capacitive voltage divider to shunt signal to ground on the low bands and provide full gain on 10 meters. Dont have to have the feature but good time to test it. It gets its bias from the bandswitch diode matrix. So you can just apply 9vdc at Conn 2.

Make sure that you have the bandswitch shaft inserted and you get all the dot/impressions aligned properly if you move the shaft around during bench testing. All wafers need to be back at 9:00 when you are ready to re-install the board.

Look at Q5 switch. You need to get it turned on. You need RLR to turn it on so you can ground the Source of the mosfets. You will need bias on Gate 1 of Q1 and AGC control voltage on Gate 2 of Q1. So you need RB1 of approx 1vdc for Gate 1 and approx 3vdc for AGC. It is actually pretty simple to do with dc bench supply and flashlite batteries.

I always try to bench test RF board whenever I make repairs to it. Too much work to put it back in and find didnt fix it. I bench test the rewound L41 and then install it back in the RF board and then test the board.

OK I mis-spoke. I am so Happy. A reader pointed this out to me. The typing is not for my health! Someone reads this junk. Just wish they wouldnt lurk in the shadows. We need people to help with this stuff.

You have not measured MDS (minimum discernable signal level). This simple test with the VTVM tells you if the receiver noise gain is typical. It is a simple test that any ham with a VTVM can do.

To measure MDS you need a good RF sig gen with a calibrated 1uv output signal. Here is procedure in case you have the test gear and just have never done the test;

1. Basically do the same set up I described and connect a VTVM or DMM across your speaker or 8 ohm dummy load. Set RF gain full CW and AF gain full CW. I would use 8 ohm 2 watt dummy load resistor so dont damage your speaker.
2. I would do this on 20 meters. Turn off the AGC. Inject 1uv (-107dBm) at 14.2 mhz. Peak the Drive control for max volume. If volume is damaging your speaker you can turn it down, but do not touch it until test is over. As noted above the dummy load across ext speaker jack solves this problem, but if you dont have one then reduce AF gain to prevent damaging the speaker.
3. Measure the voltage across the speaker or dummy load and record it. Lets say it is 1.0 rms volts. This is the S+N or signal plus noise reading.
4. Turn off the RF sig gen or remove it from SO-239. Measure the voltage across the speaker or dummy load and record it. Lets say it is 0.085 rms volts. This is the N or noise voltage being produced by your receiver. Now you need to calculate the S+N/N ratio. You have seen this before in receiver specs.

Do simple calc (need scientific calculator) :

1. Divide S+N/N or 1.0/0.085 = 11.76
2. Take log of 11.76 = 1.07
3. Multiply 1.07 x 20 = 21.4 dBm
4 -107dBm (1uv) - 21.4 dBm = -128.4 dBm
5. -128dBm = 0.089uv

Your MDS is -128dBm

Terry K9TW

Brian,

Just for info, and as Joe pointed out about radio nosie floor. I spend several weeks going crazy on my original 530s after taking out the 8.8Mhz mods for the SM220 pan display, which I might add does deafen the radio some 3Db. So using head phones I noticed a difference in the radio nosie floor, I wasted many hours going through the radio checking and doing similar test as Terry, suggested to you. I eventually pulled out my spare 530s and there was no difference. For me personally, if the tests Terry, has recommended come within spec, dont fuss to much. You may think about replacing diodes, but I doubt one would notice the difference unless hooked up to analyzers and plotting graphs. This is also assuming your radio isn't deaf. No matter what we are here to help

I'm new to hybids - in fact I'm pretty new to HF period. Been a repeater rat for 5 years. I seem to be having an issue with my 530S. I know I'm tuning it up well and all seems good but problems on transmit. I've tried two different mics as I thought it could be a short. When I transmit (I've done this on what seems to be an unoccupied frequency) my meters show what looks like I'm keying/unkeying mic - even though I'm not. I've attached link to short video I made of the issue. Thanks in advance for any help! 73 - CP

Hi Joe
Let me first say that it could be lots of things, but I would check out and clean the relays.
A weakpoint in the 530 is the band switch, clean it gently.
Just some suggestions, at least a place to start..

CP,

It seems like your getting RF feedback, do you have a decent earth connected to the radio etc? Also have you checked the earth on the mic?

Subject: [TS-520_820_530_830] Intermittent Transmit for 530S?

I'm new to hybids - in fact I'm pretty new to HF period. Been a repeater rat for 5 years. I seem to be having an issue with my 530S. I know I'm tuning it up well and all seems good but problems on transmit. I've tried two different mics as I thought it could be a short. When I transmit (I've done this on what seems to be an unoccupied frequency) my meters show what looks like I'm keying/unkeying mic - even though I'm not. I've attached link to short video I made of the issue. Thanks in advance for any help! 73 - CP

CP,

As the video is a little dark, I am basing my thoughts on you are switching to dummy load from an active antenna. Does this only happen when you swtich to active antenna and no issues when in dummy load?

Topic: 47300 Message: 47304

Hi All,

Just an update, I am currently negotiating with a distributor for the

RL-1 AF board\IF board flat pack relay for the 830 and 530 series. I am also working with knowledgeable members to ensure these are the exact relays. Hopefully these will work out with only one issue, a 45 - 60 day delivery date due to the relays being manufactured, cost is still being negotiated, but should be in or around the current price.

Further to Terry's, mention of the 530s relay FBR321D012. If there is enough interest from amateurs then I will be able to source a reasonable 1x of bulk purchase, but I will be looking to move these on as quick as possible, as it is a large outlay. Anyone interested in the FBR321D012, for the 530s, please email me off list so I can workout if this will be viable and to get the price as low as possible.

FYI I am not looking to do this as a business, just purely doing it to keep our radios and members on air. It is Friday afternoon here so may not be able to update until next week.

I dont know if its worth the trouble.
I don't know if the transformers are the same in the S and SP models,
but if they are you can get a converter from another model and hook it up.
I did look at the schematics of the 530 and 520.
The transformers look alike.
But to add the Kenwood converter looks like a lot of work. Lots of wiring.
I have three converters in a box. One went pop on an old rig when using 120AC.
Fortunately the rig was in the garage, not the house.
I think someone miswired it.
I fixed the rig, disconnected the converter.
So I never use them.

Would be better to see and focus on the the transmitting rig panel meter than the receiving rig.

Is the mic gain turned up? What are you seeing on the ALC meter on the keyed transmitter?

Turn the mic gain down full CCW on the keyed rig and repeat.

Are you switching these two rigs back and forth between a common antenna? If so must make sure antenna switch has good isolation between ports and no way to accidently apply transmit RF into the SO-239 of the receiving rig.

Brian

I have to assume this is not a new issue as I inquired about?

Let us know if you do the simple noise gain test with a VTVM.

As a point if interest regards MDS. No one can hear signals at the noise floor. For that reason MDS is measured at 3dB above the noise floor. In practice few can hear signals there with exception of perhaps seasoned weak signal CW operators. So 10 dB above the noise floor is where you see most receiver sensitivity specs.

Look at the spec sheet in your KW hybrid owners instruction manual. If you own a TS520 you will see 0.50uv on 3.5 to 21 mhz S+N/N 10dB and on 30mhz 1.0uv S+N/N 10dB. 10 meter performance isnt that good but you can compensate for it with a directional gain antenna. Usually not a problem when the band is open.

Overall performance was improved on the TS520S and subsequent models to sensitivity spec of 0.25uv on all bands S+N/N 10dB. Never seen a KW Hybrid in good state of tune that could not hear a 0.25uv signal (-119dBm).

We have not talked about listening fatigue and no one has talked about operator practice. People forget or really dont know what the RF gain pot is for and it is OK to operate it. Most simply run it wide open. Part of fun of operating a receiver is to operate it. Old timers learned to ride the RF gain pot so not always listening to high level of background noise. By riding the RF gain control you can control the range of the AGC to some degree as it isnt smart enough to distinguish between signal and noise.

If you do some fundamental testing and determine your receiver noise floor and noise gain is normal try riding the RF gain control during certain copy conditions and see if that doesnt make your listening more enjoyable.

Not saying you dont have a noise issue. Just dont know absent hands on look at your radio.

47310. Two questions on AT-230 and AT-250 Antenna Tuners

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-01-31 14:03:04 UTC
From: Jim Jezek
Topic: 47310 Message: 47310

1st Question: I have a broken AT-230 antenna tuner. The X-Tune knob is broken from the nylon shaft just behind the faceplate on the module. From what I've been able to surmise, the nylon shaft is contiguous with the rest of the components on the shaft and would have to replaced as an entire part. So, any suggestions on where I might find a replacement X-Tune assembly?

2d Question: My rig is a TS-530S running an 80-10M G5RV longwire. My Drake antenna tuner seems to work well (most of the time). But, I am looking at a Kenwood AT-250 that looks like it might do the job better. Anyone have experience with the AT-250 working with a TS-530S? I'd appreciate any insights.

Thanks,

Keith,

Are you sure you connected your DC meter probes correctly, the RED meter lead to the Rectifier Unit's 210A terminal and the BLACK lead to the Rectifier Unit's SG2 terminal?

There is no component(s) between the Rectifier Unit's 210A terminal and the Rectifier Unit's SG2 terminal, other than the Rectifier Unit's RL1 relay terminals, that would result in a voltage drop of 250 volts!!

A note of caution.

I have had two TS530 rigs here this month and both had replacement rubber front feet (not KW originals but cone shaped). These cone shaped or tapered rubber feet are being supplied with very long screws. The problem is on the left side (looking from the bottom with front panel facing you) the long screw is contacting the audio amp heat sink and machining threads in it and leaving metal shavings as it is tightened. On the other side the screw is in the clear.

The aluminum heat sink is designed with a cut out to provide clearance for the factory screw.

You do not want aluminum shavings on the audio board or dropping else where in the rig. I vacuum out with shop vac as I am afraid if I use compressed air I might drive the aluminum shavings and dust and lodge them somewhere and induce a short.

Topic: 47316 Message: 47316

Hi group!

Last time I posted here my radio was working very well (mostly) after doing a complete cleanup of all contacts on all the boards, cleaning the VFO, and re-soldering all the components in the freq. display unit. The display was stable and visible, and the frequency stayed put. That lasted 3 or 4 months. :-(

Before the holidays the radio started acting up again. The frequency jumps around 3KHz above/below the tuned station, and sometimes even more. It is not the display unit because I tune on a station, and the OM on the other side jumps in and out (with even some chirps). Same thing happens when I try to transmit and the OM on the other side says he can hear me on and off and can not make out anything I say. Sometimes, not often anymore, the frequency remains stable and I can use the radio for a little while.

Following some advice online, I re-cleaned the VFO, specially the wiper, to ensure there is proper grounding. I also removed the AF-AVR board, and cleaned all its contacts again, and even added some more solder to the board where it touches the case, to ensure proper grounding. Doing this changed nothing; the frequency still jumps all over the place.

I do remember seeing one more thing online, some time ago, about using a 9V battery to test if it's an unstable 9V supply, but I can't find that website again and I am not sure how to go about doing this test.

Any advice on what else I can try?

Thanks in advance for your help, and have a great weekend!

Cesar:

Two other things to consider for that kind of a problem:

1. The filter caps in the carrier generator board can cause exactly this kind of problem if they go bad. Over at MODS.DK they have an article on that and how to fix it. I have a copy and can send it to you if you can't find it there.

2. The PD unit (the board on the bottom below the heterodyne oscillator) has a tantalum cap, 0.22 mfd, I think. I saw in the TS-820 Service Bulletins where that cap going bad can cause noise in the receiver. I thought my 820 sounded kind of noisy compared to my TS-520 and changed that cap. I used a ceramic cap rather than tantalum. And when I put the board back in the 820 it was doing just what you describe. It appears that the wrong kind of cap in the PD board can cause that and presumably that includes a cap that has gone bad. Fortunately I had a spare PD board to put in the radio.

Good Luck!

Hi Wally,

Look for a used APC brand UPS on ebay or the swap meets,
the Smart UPS models can run off a battery w/o any AC,
autostart is the feature.

You can power the UPS with an external battery using powerpole connectors
or your favorite type of connector.

The SmartUPS series puts out a full sine wave, makes the radios very happy,
instead of a step or modified sine wave.

Often you can get them without the batteries, saves you on the shipping too,
look for a seller local to you to save on the shipping.

I've been using those feet on my rigs, really like a radio propped up in front.
Using the stock original foot with the center hole screw to add another step, I put those on for total of over an inch.
I also sit it on a 2 X 2.....gets it up in the air and I route the mic cable under and to the side.
Also gives me room to slide my hand key under Rig to reduce clutter.

I thought the supplied screws that came with those feet from Mr. Kepski were same length as stock.
Might have been changed, or because these are soft rubber, will tighten to a greater depth than the original stock screws with hard plastic original feet.

Thanks for the heads up caution Terry.

If you have the mechanical clearance and the shaft is broken in a manner that it can be mated exactly as it was, a small amount of epoxy might take care of it. Just make sure it only gets where needed. How much clearance around the break? A small metal hose clamp or a wide cable tie might help in addition to the epoxy. I haven't been inside one of these, so I can't really picture where the break is.

The knob has about an eigth of an inch extruding into the opening in the tuner faceplate. I'll have to check the clearance to see if a hose clamp might solve the problem. It looks fairly snug in the hole in the face plate so I'm leery of epoxy. I suppose I can always ream the opening a bit more to provide clearance.

I'll ask again, not having that bulletin,
Has anyone an accurate count on how many solder holes there are?
I've asked 5 times now.....unless somebody has answered and I missed it.
I counted 16 holding the one board up to a light.
None on the second board.

Did you ever perform Kenwood Tech Bulletin #26 "Service Note on DG-1" ? It's where you pull out the counter boards and re-solder all of the feed through plated holes? In addition it's recommended that the user put a wire through each feed through and solder both sides.

Or possibly a wire wrap. I've been thinking on the sprocket problem. If it's just a crack multiple wraps of finer wire may be a permanent fix.
Think of the file handles with over an inch of wire wrapped on the wooden handles.
Each additional wrap adds strength, the more wraps the stronger the mend.
Also looked at that website for sprockets, just too busy right now to explore it.

Michael,

A few minutes taken to "Google" the "Kenwood DG-1 service bulletins," would have shown you that there are
18(eighteen). All of the "through holes" or "vias" a some call them...are accessible from both sides of the board.

There is 1(one) that is only accessible from the "bottom" side as it is under an IC chip.

A fellow wanting to start a Ham's salvage business, for things too "nice" to get rid of.

If anyone wishes a copy of the information he sent to me (it is an MS Excel spreadsheet, let me know if you can't read it and I'll convert to something else, like plain flat text, for you) please contact me OFF T HIS LIST and I will email it to you same as I got it. It's got bits I think people can use for other radios, don't know if any of the parts at all (transistors) will cross to Kenwood replacement parts, haven't had a chance to look.

MIGHT have a breakthrough in relays though, hold onto your hats about those. Anyone in need of one or two relays, well, send me an email, I'm not sure how many altogether we can get.

Mark,

As I mentioned in my original post, it is not a problem with the display unit. I did do work on the display unit some months ago and re-soldered everything, and the display has been working great since then. The current problem is with the frequency itself, as I can hear it jumping around.

Thanks for your suggestion though! ;-)

I assume at no time the display goes blank?

Do you have a frequency counter? Might look at the VCO output signal and see if it is moving around.

Maybe cycle the Tun/Norm switch on VCO board?

Need stable VFO to feed the PD. Are couple of other Mixers which need stable input signals including from the Carrier and Het Oscillators.

I suppose could even be a dirty molex connector. Just need to break out the schematic and use O-scope or RF millivolt meter and Freq Counter and confirm required signals are not moving around. I would look at VFO, Carrier Oscillators, Het Osc and VCO signals for starters. When I say look I mean not only at the source but where they are used. No good to just verify VFO signal is good at output of the VFO. Need to look at it where it is used. Same with all required Osc signals.

For example OK to look at VCO on TP-5 on VCO board but also need to make sure it is right level and freq at TX and RX Mixers on RF board at Molex conn RF-1 and at TP on the board.

Michael:

If we lived on deserted island and rig was our life blood we would use tie wire, nylon cable ties, dental floss coated with epoxy, copper tube sleeves, heat shrink, JB weld, rubber bands, chewing gum, etc to "fix" these sprockets.

Everyone has different definition of quality and workmanship. Everyone has different levels of disposable income. Some dont care what their rigs look like inside or out they just want them to work and even then the definition of "work" greatly varies. I have had VFO knobs that I thought were on an eccentric and when I called customer for repair authorization they said they had not noticed. Kind of sad.

For some it is fun to do these kind of back yard fixes and for others it would not be acceptable. We are very close to having brand new sprockets that have been re-designed to address the design flaw at the tapped holes. I for one will be in line to purchase them to replace the cracked and temporarily "fixed" ones in both of my near mint TS-830s. Just the way I am built and think.

Tie wire has been previously suggested and used.

Keith,

Have you watched my series resistor video that shows how to determine a voltage drop across a simple resistor? It's an example of what I have asked you to do to measure the voltage drop across the simple 210A and SG2 terminal circuit! My series video can be found at the following link:

http://www.n6wk.com/w5rkl/Basic%20Ohms%20Law/Series%20Resistors.wmv

My next question now is:

If you say there is a 250 volt drop that is occurring between the Rectifier Unit's 210A and SG2 terminals, than what is the voltage NOW at the SG2 terminal?

As a retired musical instrument repairer I could suggest this method of repair.
If you have access to a set of mini drills and associated taps and dies you could drill a small hole in each side making sure they are both central and then tap them and insert a short length of threaded rod, and just to make sure a little epoxy to stop it moving. Or plain rod and epoxy it in.

Good morning Gentlemen!!

Just went to K4EAA.com to replace what I put into my Gold Label over the last 24 hours.
Ken just restocked some flatback relays for the 530 and 830.
Of course I ordered 20.....(no, not really).

In the Gold Label in the last 24 hours:
Replaced the HV caps, no 0's this time!

New Blue relay, with custom seal, (explain later, remind me!)

New Cathode 20's, had a 0, 116, 166 and a 198.....pegging IP in tune.

Band switch coupling, old one broken and glued! Fun to get out!

Neutralized with new scope, bought a beautiful used Tektronix with a superb manual that includes calibration specs!
Looking at 6146B to order, anyone use the Taylors from RF Parts?

$46 a pair, not bad.
She's on the air with the Breakfast Club. Strange band conditions this morning about 6am CT.....short, long, short ,long.....
Getting good signal reports and she's working GREAT!!
(Once I figgered out the VBT!, man that sounds weird when way CCW....)
Wow, what a receiver!!!!!

Anyone know where THOSE can be found? And the cross-over number to the Panasonic or other brand, since the Omron type seem to also be unobtainium.

I figure I ought to snag a spare for myself as well. The NOS exact replacement I spotted on the web was a laughable $70; nah, I don't think so.

Who has this one? Where, how much should I be looking at paying? So far, knock on formica, there doesn't seem to be any problems with either of the relays in my 520SE, but I'm starting to think I should plan for the future.

I must confess that I am very puzzled as to why the 6146W's were so different. Has anyone done some measurements on them at all? Or is it a more subtle thing like inter-electrode capacity changing the neutralisation settings?
Oddly enough the only TX tubes I have ever had problems with were from Philips!!!
So unless the Taylor tubes were actually faulty or "soft" it is a mystery.
I use some selected 6146B's in my TS820S and they go fine.

I had been buying and using these relays from Ken for some time thru mail order. I bought 4 more of them when I attended Kalamazoo hamfest last year and I have installed them in 520 and 820 and they work fine. I cant say about longevity, but appear to be same as the original Ant TR and Aux relays. Ken does not have a data sheet. I hope he still has them as he was running low on stock.

I took samples of all the other KW hybrid relays and Ken could not match any of them. He bought out the inventories of major CB manufacturers after the heyday. His cramped store (in an old house) is fun to visit and amazingly he knows where everything is at. You might also try him if you need any transistors or mosfets.

6146w is a military or ruggedized version for mobile (high mechanical shock and vibration) service.

I have used JAN 6146Ws for a long time. Most have been ECG/Sylvania. Bought them from RF Parts last several times and they came in a white JAN box and work just fine. Running them now in one of my TS830 rigs. Never had one arc over. They hi-pot to around 2500vdc. They have same inter-electrode capacitance as a 6146B and neutralize just fine.

Some folks dont like them because the plate dissipation has been de-rated to 25 watts so they believe cant load to 100 watts out, but in my experience will easily load to 100watts output and run ICAS service all day long.

I prefer RCA 6146B when I can get them, but the JAN 6146W is a fine tube for your KW hybrid. I would not hesitate to buy them from RF Parts.

Terry-

I am going through a very nice TS-520SE that has a very raspy CW note. The receiver sounds great, there is no hint of raspyness or AC hum. I listened to this TS-520SE using two different receivers to verify the raspy note, it is raspy sounding even with the S/G switch off and listening to the driver stage. Any ideas where to start? I have already replaced the 2 of 2200 uFD at 16 VDC caps in the LV supply. Thought I may ask before going to much further with it.

Thanks, Byron

Say - I got that other TS-520S ALC problem fixed, it was Q-10 ALC transistor on RF board.

Well the Carrier Osc, VFO, and Het Osc are all three used in Rx and Tx mode as the LO for various mixers so if receive audio is good then I would think these signals are clean.

Replacing the caps should mean you have clean 14vdc to the AVR series pass regulator which means your 9vdc should be clean.

Question: What does SSB TX audio sound like?

About only thing different is the TX Mixer is involved now. Although it uses same Het Osc for LO.

I was thinking about problem with the Balanced Mod (is a mixer) as you inject Carrier Osc there to produce DSBSC output and if have leaky diode can be a problem but should also manifest itself in Tx SSB signal.

Easiest thing is to look at output of these Oscillators and Mixers with O-scope and having two TS520S rigs can make comparisons of what good signal looks like vs bad signal.

I would probably look at output of Balanced Modulator. You can do that by getting on the Gen Term post at Gen board and IF board.

You could also look at TIF signal at output of IF board and at TP-2 on the RF board. It wont be nice clean sine wave as Het Osc leaks back.unless you have pretty good O-scope with filters that you can switch in. Of course as I mentioned you can compare the signals with the good TS520s.

I would tell you to replace the Bal Modulator diodes but I would be guessing. Probably easiest place to look with your O-scope would be at TP-2 on RF board for starters. Dont like to start replacing components unless troubleshooting indicates that is the source.

Byron

I forgot to ask if you have a frequency counter? If so might couple a loop with few turns of wire around the driver tube and feed it to Freq counter and see if the RF drive signal is FM-ing. Can do this with SG switch off. Again this should effect SSB transmit as well.

Common cause is VFO power supply ripple. Also, might have 12BY7A heater to cathode leakage, but I would think should get bad audio reports in SSB mode as well.

There is a Heater bypass capacitor and choke, but never seen them bad. C35 on the RF board. That is about all I can think of and have to tell you have never had any hybrid with raspy Tx CW note.

Try another 12BY7A.

Terry K9TW

47358. ++ Wow - nowaday brand new TS-830S

Thanks for looking around Gentlemen. I really do appreciate that.

My "Goldie" Quit just before another check in on the Breakfast Club yesterday. Was working perfectly. I was using an odd ball set of tubes, one Philips and a Khainese. Cursory check of cathode R's shows high,

So something is causing them to blow.

Has anyone had any luck with the new Khainese tubes?
I think last time that subject came up the general consensus was they had insuficient history to determine if they were consistent or to accurately judge their quality or lack thereof.
I did buy a set for my first radio when I first got my ticket oh so long ago,
in September.
I think I recall they ran 'hot', at about 110 watts.
Don't clearly recall the brief history of their performance
but I'm down to one.

I'm going to find my 'issue' with Goldie and try an old set of Mitsushi's in her.
They tested weak, under 80% but should tide me over.

Thanks again guys. Grab some relays!!

"How can I know who I am until I know who I was?"

Man am I sick of swapping cathode resistors.
I still get a brain fart and mix words, cathode and grid when on that subject.
Idiot savants are like that, especially me, just leave off the savant part.

Found some NOS Motorola 6146B's cheap. Anyone have any experience with those? Need to stock up.

What are most likely causes of frying Cathode resistors other than funked up tubes? Already changed out the HV caps and relay with new.
spent a buncha time going through my old tubes pile and got a decent set to run "Goldie" with, good signal reports from around the country before 75 meters went south Trying some CW this morning on 40.
Busy with other things though, eBay and such.
Think Goldie is about finished for now. Wow, what an impressive radio. She's got more doo-dadds to change sounds of incoming audio than I could've made up on a drinking binge.....
Love her already. Even more than the refurb TS-530S I sold 2 weeks ago. I was getting real fond of that one.....
At first I didn't care for the itsy bitsy knobs....I'd been using TS-820's for the last 3 months since getting my ticket in September.
I've got giant hands and the larger controls and bigger face are more suited to my inherent clumsiness.

Terry, thanks again for all your time devoted here. A couple of real early morning posts today are very informative.
The circuit for diode protection of Cathode resistors will go into Goldie before I put her clothes back on, thanks for the detailed explanation of that .I found this digging through archive files.
You all have a great day!!

47361. Kenwood Hybrid Net Update (February 2, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-02 20:41:49 UTC
From: Mark Gilger
Topic: 47361 Message: 47361

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday 40 meter net had 19 stations checking in under good band conditions. There were 2 new stations checking in, KK4RXN, and KC9AZ. We had the following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
3 running TS-820(x)
3 running TS-830S

I was running my TS-940s with an L4B amplifier.

The Sunday 20 meter net we had 12 check-in under good band conditions. There were no new stations checking in today. We had the following number of radios.

3 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
3 running TS-830S

I was running my TS-820/R-820 twins with an L4B amplifier.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can

alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 19, Sunday☐s total = 12 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

47363. Re: [TS-520_820_530_830] TS830S No Output

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-02 20:55:51 UTC
From: Mike W5RKL
Topic: 47087 Message: 47363

Keith,

If there is +242VDC on the Rectifier Unit's SG2 terminal then there is a 8 volt drop across the Rectifier Unit's RL1 relay terminals. This can be caused by corrosion or dirt. An 8 volt drop shouldn't result in a 50% voltage drop to the final tube screens.

Now, with the 830 turned OFF, the main power plug pulled from the wall socket, and the caps allowed to discharge to 0VDC, perform the following resistance measurements "exactly" as I have indicted below. In other words, make absolutely sure you have the meter leads connected to the Rectifier Unit terminals I have indicated and NOT to the chassis!!

Set the MODE switch to either USB, LSB, or CW position but NOT the TUNE position!!!

Set your DMM meter to measure "Resistance". Set the DMM's resistance setting to the lowest resistance, typically 200 ohms.

Now connect the Positive RED lead to the Rectifier Unit's SG2 terminal and the BLACK lead to the Rectifier Unit's SG1 terminal and note the resistance, it should be a very low resistance, almost zero. It's okay if the resistance is 1 or 2 ohms, that could easily be the meter lead resistance.

Next, leave the RED lead connected to the Rectifier Unit's SG2 terminal but move the BLACK lead to the Rectifier Unit's PD2 terminal and note the resistance, again, it should be a very resistance.

Let me know what both resistance measurements are.

Now, move the RED DMM lead to the Rectifier Unit's "PD2" terminal and move the BLACK lead to the Final Unit's "SG" terminal and note the resistance. It should be a very low resistance.

Let me know what the resistance is.

Next, move the RED lead to the Final Unit's "SG" terminal and the BLACK lead to each final tube socket pin 3, note the resistance of each socket's pin 3, they both should be approximately 100 ohms or within 10% of 100 ohms.

Let me know what both tube socket pin 3 resistance readings are.

Okay, I bit the bullet and pull the RF board out, disassembled the switch. I found 3 different contacts that were not being made even though the rivets all looked pretty clean. I soldered all the rivets and checked all were < 1 ohm across the switch. Put it all back together and tried it out.

Good news and bad news. 10M now has ALC, but I lost 160M. No freq display at all on that band.

Michael,

Why do you think the final amplifier cathode resistors are failing?

1. Improper tuning of the final amplifier

2. Arc inside the 6146 between the plate and beam forming element

3. Aging carbon cathode resistors

4. None of the above

Did you try Quartslab?
They are in England and I believe they are less expensive.
I ordered eight custom xtals for less than $200.
e mail:
sales2@quartslab.com
they will give you a price.
They appear to know what the xtal characteristics should be.
I assume you have also tried kenselectronics.com in Grand Rapids Mich for NOS xtals.

Well I understood from looking up the data that the 6146B was an
upgraded 6146A.
Mainly that the anode (plate) design was changed and the plate
disappation went up from 25 watts to 30.
Certainly 6146A's struggle in the TS 820S final at high powers!

When ever I do bandswitch repair I do all the contacts on all wafers and not just the ones where I can pivot the contact back and forth around the lose rivet head or where I read high resistance with an ohm meter. You can screen the contacts with an ohm meter and rotate the wiper back and forth to look for high resistance or intermittent and just solder those, but when I take time to pull the RF board I just solder all or apply jumper to all. I dont want any rework for the customer. .

Using an ohm meter to check the contacts is not the best method. If you apply 6vdc current limited to 1 amp and measure the millivolt IR drop across the contact you will find more bad contacts. Should be less than 100mv which is 100 milli-ohms.

Also have to make sure get all 12 pins on each deck soldered back to the board. It is easy to lift a foil on the two pins that have been folded over to secure the board for soldering so when you resolder make sure any pin that has lost some of its pad is oriented to where most of pad remains to resolder.

Give Dick Housden W0NTA an email asking for some tips on how he approaches bandswitch repair. He probably has best track record of anyone I know.

Chris:

Some people believe that a pre-1964 6146W is a "premium" 6146A and a post-1964 6146W is a "premium" 6146B. I dont know where they get this stuff from. You wont find that in the data sheets.

I have never seen an A or B designator marking of any kind on any 6146W tube. A 6146W is commonly marked as a 7212.

I have used RCA and GE and most commonly Phillips/Sylvania brands. The JAN (joint army navy) Sylvania that I commonly use have 79 and 87 date codes on them. In fact I have never seen a 64 date code.

Frankly I see all types and combinations of 6146 tubes in the rigs that come across my bench even mixed brands and mixed designators and they all seem to work just fine and neutralize just fine. I dont run my personal hybrids that way, but I think much hype and worry about nothing.

My advice is read the manufacturers data sheet. As I mentioned the 6146W that I am familiar with is rated at 25 watts plate dissipation (some data sheets will show a minimum of 42 watts output).

With a common Ip meter and common bias pot we have no way of adjusting or determining how well the tubes are sharing the load. While certainly dont need matched pairs I think best to stick with 6146B or 6146W and I tend to do that with same manufacturer so you know same build parameters.

The reason I ask is because I could use some fresh back ups for my Heathkit Apache. I have been having a blast with that rig on AM.

From the 6146 family of tubes:
Also, I know of no "master list" telling on what date
a particular manufacturer changed from the 6146 to the 6146A to the 61468. The
only "sure" way to know if a particular 6146W is of either the 6146 or 6146A type
is to look for a "code date" of before 1964 since RCA introduced the 61468 in the
middle of that year. However, some manufacturers did not start manufacturing
61468 equivalent 6146W tubes for at least a year after RCA introduced the
61468.
This article is in the files.
Hope this helps.

No, I didn't, the people at ICM were the only ones recommended when the question was first posed, really.

> I ordered eight custom xtals for less than $200.

That's about exactly the price I got the two for, comes to just about $25 each, shipped. Had I ordered eight instead of two, the shipping would have been the same and they would have cost a few pence less than $25 each, but not enough to bother figuring or fussing with.

> They appear to know what the xtal characteristics should be.

As did ICM, but they were worried that the rest of the circuit had slipped far enough out of stock specification to make the crystals require a little different internal capacitance measurement. They were willing to adjust that specification for free during the manufacturing process. Since they must choose what it comes out as when they cut, grind, and lap the chunk of rock anyway, picking a modified value at the outset wouldn't be any problem at all.

> I assume you have also tried kenselectronics.com in Grand Rapids Mich
> for NOS xtals.
> Wally
> KC9INK

Actually, no I didn't, truth be told. I skipped the NOS option, because that was mentioned to be a complete HET-OSC board and a full swap, and I want to keep this one. Nothing wrong with swapping boards, I did that with the rectifier board already.

But I want to get a good look at this one, see what they did to it when the idiots swapped the crystals to the CB spec., and the skill or lack of it used there will either ease my mind a bit if it was done competently, or warn me to keep looking for more evidence of ham-handedness (rather than ham-radion-ess, I suppose....).

Besides, the cost was about the same for either option. Perhaps a little less for the new crystals. And I got to make a new business acquaintance at ICM, by the way Sara says to say Howdy to you guys who have been customers. Nice person. Knows her business.

Thanks for the reply, Wally. See you on the radio, perhaps.

I ran an Apache and SB10 ssb adapter in the middle 70s, but dont remember the neutralizing circuit. I dont recall if it has an air variable cap or uses the gimmick capacitor wire protruding near the finals?

Mike W5RKL would likely know. A lot of folks report neutralizing problems with Heath rigs using different 6146 finals. I cant comment on that. I ran HW-101 and SB-102 but cant remember what variety I used. Whatever they were I had no problems.

I just have never experienced any problems with any of the KW hybrids not liking any particular 6146 final. I would not use the Taylor or Penta chinese made 6146 tubes as I think they are building them for Yaesu and Heath transceivers and dont realize that the Kenwoods run about 100vdc to 150vdc higher anode voltage.

I just like to use 6146B RCAs when I can primarily for the higher plate dissipation.

Glen Zook seems to be the one who believes firmly in differences in the tubes and inability to use in some rigs and neutralize in some rigs. Tom Rauch W8JI counters that to say he runs any and all in his various 6146 boat anchor rigs. I dont get involved in that debate, but have to say my experience more aligns with Toms as far as KW Hybrids go. I just had a TS520S here with a 6146A and a S2001A on the bench and it loaded and neutralized just fine. I offered to install NOS 6146Ws and customer declined.

Might want to post on the Yahoo Heathkit forum to see what the Apache and DX-100 owners are running.

One thing we tend to overlook is that in the 70s and 80s we were buying new rigs or kits with new manufactured 6146 tubes installed or if we did on the rare occasion buy a 6146 tube it was a new tube. Today we are buying pulls, NOS, and supposed NOS tubes that are 30 to 40 years old and then wonder why we have problems (ie arc over events).

I think I have read forward compatibility is not the issue. The problem arises when we use 6146B's in some old radios. They go parasitic. I have a friend that is running 6146B's in his Apache. He has no problems, but I have heard bad stories in other older rigs. 6146W's should not be a problem in hybrid rigs -- either way.

Indeed the Benton Harbor Apache uses a gimmick wire that you move between the two tubes to neutralize lead inductance and self resonance.

That rig is a BEAST, but I won't digress anymore about my fun radio :D

The Heath Apache TX1 transmitter as well as the Heath Marauder HX-10 transmitter, I have both, run 6146As.

The final neutralizing capacitor in the Apache TX-1 is a vertical wire running up the side of and between both final tubes. The wire is moved closer to or farther away from the final tubes when neutralizing the final amplifier. Not an easy methode of neutralizing the final but it works.

The Marauder HX-10 uses a variable cap to neutralize the final amplifier.

Heathkit performed tests with different types of 6146 tubes, As verses Bs in the HW-101 and found, early on, that 6146Bs didn't appear to neutralize very well in the HW-101. However, in May 15, 1979, Heathkit's HW-101 service bulletin, "HW-101-49" stated the 6146As were no longer available from the manufacturer and Heath had tested "GE" brand 6146Bs and found they neutralize in the HW-101. Heath, once their stock of 6146A ran out, they provided GE brand 6146B with the HW-101 kits.

There are 2 differences between the 6146A and 6146Bs

1. Plate dissipation in the "A" is less than the plate dissipation in the "B"
2. The 6146A Grid #1 to Plate inter-electrode capacitance is .24pf while the 6146B Grid #1 to Plate inter-electrode capacitance is .22pf.

The ".02pfd" difference in inter-electrode capacitance between the "A" and "B" should not make a difference when operating in the 2 to 30Mhz HF spectrum. Moving up to VHF and above, the ".02pd" difference can have a significant affect on stability in an amplifier when using either the "A" or "B" versions.

I try to run 6146As in my Heath transmitters and transceiver, primarily because they are cheaper. I also don't push the daylights out of any final amplifier running any vacuum tube, whether it's a 6146A, 6JB6 sweep tube, etc., so the difference in plate dissipation in the 6146A/B is not an issue.

One should never mix a 6146A with a 6146B. One should use two "As" or two "Bs", never one "A" and one "B".

Also, I see where a lot of people seem to rely on a tube tester to determine if their 6146s are good or not. Remember, a tube tester cannot and will not test the 6146 in the same manner as the actual RF circuit the tube will be used in. The best tester you should use to test 6146s is the actual circuit the tube will be used in. A tube tester can test for physical element shorts, open filaments, and "basic" conduction but

that's about it. I had one of the two 6146Bs in my HW-101 that arced. I tested both tubes in my Eico tube tester and both tested GOOD. The tube tester did not test for gas which is what caused the arc so the test was "misleading". The indication, other than the arc, that told me the tube was bad was the bad 6146 became warmer around the base of the glass envelope much faster than the good 6146. I replaced both 6146s with NOS 6146As from vacuumtubes.net, problem solved. No, the arc did not take out the "6" 10 ohm cathode resistors. The total cathode resistance is "1.6 ohms". With 250ma indicated on the PLATE meter, the cathode voltage is .415 volt (415mv). Never had problems with cathode resistors failing in any Heathkit 6146 final amplifier, even when that 6146B arced in the HW-101. The old carbon resistors would increase in value causing invalid PLATE meter indications but no blown/burnt/exploded cathode resistors.

Yes we probably should move on. I have never seen a KW hybrid 6146 final with a "parasite". Seen a few with thermal runaway, but no VHF parasites. I sometimes wonder about wrong cause and effect? More than one way for the plates to glow cherry red. No sense in getting into what could turn in to a passionate debate. Just keep those anode suppressors and screen grid stopper resistors in good shape.

Enjoy that Apache. I remember the day I could finally take the 2x4 stiff leg out from under hollow core door I was using as the bench top! Man real diecast knobs and modulator and plate transformers you could barely lift. The word quality comes to mind. I had some VFO drift that the Heath engineers helped me with by providing a pack of NPO caps for free. Otherwise it was flawless. They were a great company. Reluctantly replaced it with my 1st new transceiver a HW-101 as KW hybrids were not in the budget. HW-101 was fun and glad I didnt miss the experience.

ENOUGH!

One way to prevent flash overs is to use your backup tubes every now and again. Let that getter do its job of scrubbing and returning to a hard vacuum. Also, I have noticed that the mirrored Cs/Rb coating on the inside of the tube will get more transparent and eventually turn white when there is too much gas. However, at that point you might beyond the point of flashover.

What issues are they having with the Chinese tubes? If I had a beater rig, I might have a go. I have heard mixed results. I am thinking about home brewing an AM transmitter and there are brand new Chinese 813's. It seems it might be an issue of quality control. Some people have no problems while others have melt downs.

I found an explanation, although brief, in the archives, in one of Terrys' long detailed replies to one of my questions months ago.
I "replied" to that early this morning.

Yes, I definately will be adding that upgrade, prolly to all radios opened up from now on.
I'll need to pick up a supply of the needed components though. Where? Recommendations?

Initially I thought only the diodes were required, as per Terrys' directions in archives.
Thank you for that link.
I'm wondering where to find the wealth of information on other information sights that many of you are aware of but I haven't a clue how to find.....
Anyone care to share? Or is there another list in the Homepage I haven't found?
Goldie did well today on 20 Mtrs. Worked some code with a gentleman in Texas. I think I have my flagship rig.

I'm still holding my breath for moderators to release one of my posts from many hours ago asking about Motorola 6146B tubes. I found a few but have no knowledge of their value.
I definately need to stock up.
Back after the ice storm that hit Arkansas and towards NE from there maybe 2 months ago, I talked to a man that was on batteries. No electricity. All power lines were down with 1" of ice. Cell phone towers were down. He was staying warm by tending his fire and entertaining himself with his SW rig, prolly keeping his hands warm too!
I have searched for his contact info 3 or 4 times. Can't find in my log or the stack of legal pad notes I take when on air.
He said he had a stack of Sylvania 6146 that he'd let go cheap.....
I need to keep better files!
I'm thinking of buying all the Motorola but sure would like someones' input on the past quality of these tubes.
Thanks everyone.

I am in the process of building a linear(gathering parts stage) and I need to know just how to interface it with my 530. The manual does not give specifics about that. I down loaded the manual for the TL922 and it looks as though the 530 provides a path to ground for the relays in the TL922. I need to know what is the max. voltage that the 530 can stand and the max. current that it can sink.

Excellent source of tubes, thank you very much.
Also has sweep tubes in good quantities. 6JE6 or 6LQ6 or 6MJ6.
Might have to fire that old LA-1000 amp up again.

First failure I have no idea, they were bad when I bought the radio, (another "it works good!") just now getting around to working on it, they were newer metal film type. One HV cap had been changed, they didn't match, now new. Flatback relay has date of 1 year ago for change, antenna relay was swapped for a blue from Hybrid. Bandswitch coupling replaced, old one was busted AND glued, that was fun. Minor attention to Wafers, no spraying however, no brushes, in pretty good shape.

The second failure, yesterday, after my first replacement I believe was from funky tubes. The last time I'm sure of the cause, which I'm shy to admit to!!

I didn't like the routing of one of the final tube anode connections, it was a bit too close to the plate cap for my liking.
After moving it away from the cap, closing the HV cage, held with one screw for now (still testing her out), Power on and loud POP!!
Dangit.

Some dipstick had the anode resistor a bit too high, it arced to the HV cage cover.....

One good thing, I've gotten real smooth and neat with replacing the Cathode R's!!
Couple new things I do,
pull the wire wrap pins, removing the wraps, removing old solder from board pads. I find a higher wattage iron quick melt and a "smack on the table" to remove the old solder is less heat damaging than anything else. I have differing wicks but no solder suckers and definatley don't have the heated device you men were discussing last week. (I have ordered 3 different solder suckers, never cared for them 40 years ago, I hope they've improved!!).
After removing the posts, clamped in hemos unwrapping with big iron, cleaning the posts.
After gently reaming the de-soldered holes with pin vise holding that diamond burr, Posts are gently wedged back into place, just through the board, resoldered with silver solder, 1/4" of wires stripped to remove old damaged insulation in most cases, I form a 3/16" U shape.
This makes it much easier to remove next time.....
I was doing 1 1/2 wraps then soldering but tough to get off without too much heat, should one need to do again.....
When resoldering the fresh board I'm using heat sinks at bases of pins to prevent heat damage to foils.
I've found that clear nail polish works pretty well to rebond foils that have worked loose. lightly wet the area under pad, do my soldering with as little heat as possible, making sure pad is down, the heat will set the polish.
Another layer when done.

I think I'll pull the Very Good Penta tubes I have in the beater 820S I've had on air for a week and Put Goldies' clothes back on for now.
I just received the first of 2-TS-430S units to troubleshoot.
The first I think is mainly a mic problem, I've ordered a new mic for that already (it's a really old CB mic that's especially nasty, cord is antique as is mic). While waiting for

the new mic, next on bench might be:
I've got an itch to do one of my better 820S units with my VFO fix and an 18 hole solder fix. Finding the other 2 holes this time!!
Then I'll have a Very Good TS-820S online too.

Still holding my breath for any ones' opinion before I drop $$ on a bunch of NOS Motorola 6146B's.
Anyone have any history on those?

Hoping you all had as productive a weekend as I had.
I'm really lovin' the 830S, "Goldie".

A simple seal for the 830S relay:
One last improvement, when working on bottom of radio, the relay presents itself as right side up.....
flip radio over, "right side up", however, it is upside down, unsealed, with a crack around the plug it seats into...with unsealed case....right in front of the fan. It's own workings speaker, and the fan constant sources of vibrations. Small albeit, but enough that the dust brought to it by the constant air flow will work into the case.
Remedy.....
I applied a "Patch" of electrical tape over the plug the relay seats into. Extending 1/4" around outside edge of female plug, stuck to the underside of chassis.
The relay easily cuts through the tape. The receiving plug has been wetted with Corrosion X, using tiny artists' brush into the female holes.
The pins of new relay are stainless wire brushed and also wetted. The pins are canted or twisted just slightly to get a better "cutting contact". After plunging the new relay into and out of the plug a few times, working in circles while doing so, it is removed and excess wetness is removed from sealing surface and from relay face.
Relay installed, cover replaced.

This eliminates the constant source of dust from the continuous flow of air from above through the cracks.
There was long discussion of sealing/not sealing relays a couple or 3 weeks ago.
Simple solution to an old problem. Had the relays been mounted cover up there wouldn't be a dust catching situation. I feel this eliminates most of the source of dust fouling the relays in this type mount.

Yup, the I.S. shorted out the Anodes causing last Resistor failure.....Dash.

Mark I already sent him there some time ago(See below)

It appeared to me he did not do the entire process. I could be wrong so suggesting here that he contact Dick for additional insights. For example what to do about lifted pads where pins are folded over, how to ensure vertically plumb on re-install, do you solder all or just those that you measure as "bad" etc.

Here is what I previously suggested:
Go to Ron WB4HFN website and look under the Kenwood Net Home Page and look under Articles and you will see Dick Housdens excellent procedure and close up pictures of the vertical band switch boards.

You can also go to Ken K4EAA site and see his pictures. Ken uses the silver pen method and Dick uses the solder method. I have done both and only do solder now.

Some folks apply the solder and a small jumper wire back at the contact hair pin turn window to keep the heat away from the contact for fear of losing spring temper. I have done it both ways and if you have very good clean bright metal at the rivet (I also apply a drop of liquid rosin flux) you can get in and out pretty quickly. It doesnt take very much solder to bond the rivet, contact material, and pc trace together electrically.

Hello Friends,

I'm new to this group.
But, there is a reason why I joined: I manage to get a brand new TS-830S.
Yes, brand new. It is quite a story.
Please, check it out at ts830s.blogspot.com

I wanted to share it with the group and also hear any advices you may have for me.

Thanks a lot and 73!

Marcio Pocciotti

Nice work. Please remember to sign your posts with your name(which you have done) and, your call sign(if any).- WB7UQU

Now connect the Positive RED lead to the Rectifier Unit's SG2 terminal and the BLACK lead to the Rectifier Unit's SG1 terminal and note the resistance, it should be a very low resistance, almost zero. It's okay if the resistance is 1 or 2 ohms, that could easily be the meter lead resistance. ----------0.2 ohms

Next, leave the RED lead connected to the Rectifier Unit's SG2 terminal but move the BLACK lead to the Rectifier Unit's PD2 terminal and note the resistance, again, it should be a very resistance. ----------1.8 ohms

Let me know what both resistance measurements are.

Now, move the RED DMM lead to the Rectifier Unit's "PD2" terminal and move the BLACK lead to the Final Unit's "SG" terminal and note the resistance. It should be a very low resistance.----------0.2 ohms

Let me know what the resistance is.

Next, move the RED lead to the Final Unit's "SG" terminal and the BLACK lead to each final tube socket pin 3, note the resistance of each socket's pin 3, they both should be approximately 100 ohms or within 10% of 100 ohms.---------103.1 &103.2 ohms

Let me know what both tube socket pin 3 resistance readings are.

73
Mike W5RKL

I have added the readings to the ends of your questions hope this makes sense, again many thanks

47395. TS-830S Dead on 160M and 10M lower portion

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-03 22:00:12 UTC
From: <wa2gju@...>
Topic: 47395 Message: 47395

My TS-830S is dead on 160M, and the 10M only at 28.000 to 28.500. During receive on 10M can hear some signals (albeit weak) and no movement of S meter even though on my other receiver they are very strong. I suspect the band switch wafers but not sure where to start to troubleshoot which section and which contact. Can anyone help point me in the right direction. I recently cleaned the switch with spray contact cleaner which took care of intermittent contact on 80M.

Topic: 47087 Message: 47396

Keith,

The resistance values you provided clearly indicate there is nothing wrong with the voltage path to the final tube screens, pin 3, starting from the Rectifier Unit's 210A output, through the MODE switch and ultimately to the Final Unit's tube's screens on pin 3 of each final tube socket.

Setting the MODE switch to USB, LSB, or CW, should result in the Rectifier Unit's 210A +245VDC be applied to pin 3 of both final tube sockets! There is nothing wrong with the voltage path where the Rectifier Unit's 210A "+245VDC" flows over to the final tube screens on pin 3 of the 6146 tube sockets!

Keith,

I forgot to mention.

The "1.8 ohms" found between the Rectifier Unit's SG2 and PD2 terminals is the coil resistance of choke "L1" on the Rectifier Unit.

The two screen resistor values on the Final Unit, "103.1" and "103.2" ohms, are well within 10% tolerance of the 2 screen resistors so no need to replace them.

No problem. I am very appreciative of Dicks work and try to direct people to his nice write up when I can. There are some nuances that he hasnt covered like how to successfully unsolder the two pins that are folded over and if he does all rivets or just those he deems have high resistance etc. Maybe he can cover that in the next rev. I am glad he covered the molex connector, driver tube and VC-1 thru VC-3 solder connection inspections and L36 problem.

I am doing a TS830 bandswitch rebuild now and just about finished and hope it will resolve the problem on couple of bands. I am still trying to decide of Tarnx is better than the glass top stove cleaner or not. I am using Wierman brand and I am not so sure that the Tarnx isnt just as good. I do like using the Everclear for cleaning as opposed to the Denatured alcohol I was previously using. Just have to be careful not to take too many hits off the bottle!

Yes I hate new format as well. The old wasnt broken. The customer is never asked or involved when the designer makes something new and improved.

Some more detail, while I had the switch apart, I soldered all the contacts. Had to scrape the board traces to get a pad that would take solder. The did a final check on each wafer to verify there were no shorts and the continuity came all the way to the wafer pins.
Yes, I ran across the issue of bent pins mucking up the traces, in that case I had to bend the pin back toward what was left of the trace and solder it together. Checked it with ohmmeter and it read good. I assume I had all the switches vertical since I didn't solder it down until the entire assembly was back together. The shaft of the bandswitch slipped through all the wafers without any problem.
One thing I didn't check when disassembling was that all the wafers index to the shaft the same way. There is a notch on the center plastic piece that the shaft goes through. When assembling, I lined up all those notches the same way.
At any rate it's kinda disheartening to have so much worse results after the procedure.
I gained ALC on 28M, lost everything on 1.5M, lost ALC on 29M and 24M.

47401. New (to me) TS-830S Station

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-04 01:42:30 UTC
From: <joe.dale.hardin@...>
Topic: 47401 Message: 47401

Hello all,
I just bought a TS-830S station including a SP-230, SM-220, VFO-230, AT-230 and MC-50. Also included was the AT-250. The TS-830S has low output, cracked sprockets, and needs some cosmetics. The rest of the station will need just cleaning up for now. I plan to restore the entire station as I have time. My last restoration was an R-390A, so I know what I'm in for. Other than finding out that the Kenwood Hybrids are great rigs, I found out that this group is very helpful to those who are new owners and who are restoring these rigs. The availability of group expertise is very important to me because I know I will need help. Anyway, I just wanted to introduce myself so, in the future, everyone will know who is asking all those questions :).

Now, the various parts kits are arriving and the adventure begins. Firs task- take on the low output problem and see where that leads me.

Dale KS4NS

47402. Re: Re: [TS-520_820_530_830] Raspy CW note

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-04 02:26:20 UTC
From: Byron Tatum
Topic: 45334 Message: 47402

Hello Terry-
Here is my progress on the rspy CW note in my TS-520SE, if you have time to comment:
I used my R-390A to listen to these frequencies, with the gain cut way back and AVC off, with VFO near 360 KHz and on 3.5 Mhz band:
1. The VFO at 5 Mhz range -- sounds like a pure CW note
2. The 8.0 Mhz bandpass IF range -- sounds like a pure CW note
3. The transmit signal near 3.860 with driver tube installed -- very raspy
4. The transmit signal near 3.860 with driver tube pulled -- sounds like a pure CW note (but much, much weaker).
So, I am assuming the issue is in the driver stage, correct?
Tonight I plan to study the driver section schematic for possible suspects.
Thanks for all your help,
Byron WA5THJ

Dale,

Welcome aboard! If you have not already, go to the groups "Home Page," and under the photo of that wonderful Kenwood station, on the left, click on "conversations." Then look above the picture and you'll see an area to enter search criteria. Be specific as possible here..because if you enter "low output," you'll get too many returns and go insane or, blind. Enter say:" TS-830S low output" to start. You will be able to go through previous posts/questions regarding that issue and more than likely find the solution to your problem.

  Please feel free to ask questions at any time if unsure.

  Enjoy your time here with us

>Hello all,
>I just bought a TS-830S station including a SP-230, SM-220, VFO-230, AT-230 and MC-50.
 Also included was the AT-250. The TS-830S has low output, cracked sprockets, and needs some cosmetics. The rest of the station will need just cleaning up for now. I plan to restore the entire station as I have time. My last restoration was an R-390A, so I know what I'm in for. Other than finding out that the Kenwood Hybrids are great rigs, I found out that this group is very helpful to those who are new owners and who are restoring these rigs. The availability of group expertise is very important to me because I know I will need help. Anyway, I just wanted to introduce myself so, in the future, everyone will know who is asking all those questions :).

No - single rig going through tuner to wire dipole. What you are seeing me switching is the tuner between dummy and live "pass through" ANT1 to my antenna.

The problem occurs when using "send" key as well as mic - so that seems to rule out mic. I believe my problem is a relay. Reading Jim Shoker's website, HybridRestore.com, the relays do go bad - in theory through an over current situation.

I'll try to access, but I think this is a sealed relay. Also seem to be hard to get.

Thanks again for input for this Hybrid Newbie. I need to get this TS530S on the air!

Hello Marco,
I have just read your blog with the beautiful photos and I am very impressed! You have a right to be proud of your purchase and I hope you will keep the radio and treasure it for a lifetime. It is especially nice since your father owned two TS-830S rigs! I am the proud owner of a TS-530SP, but would love to get a nice 830S.

Dave:

I dont align with a notch in the oblong center hole?

There is a circle indent on each wafer (white plastic) and I place all of these at the 9 oclock position. One tip for future I recommend first timers remove and repair one board at a time starting with the Drive coil board at the rear of the shaft. No way to mix them up and easy to re-solder and make sure the board is plumb as the thru bolts and other boards will help align it. If not vertical you can bend in place but dont want to do very much back and forth movement of the flat pins as they can crack and break off.

Also be very careful about bending the actual contact fingers. Some recommend pressing down on them gently with finger nail during the cleaning step. If you do that in to the open window without the wiper between the two sets you can actually push it down too far and when you rotate the wiper it will hit the edge of the contact finger and twist the contact. Now you are in real trouble.

If you look at the contact finger under magnification you will see each edge has a bent up wing to guide the wiper into the gap and spread the contact fingers. Very rare to find any contacts that have actually lost their spring temper and the source of the high resistance. I have found them where some one mucked them up putting some kind of cleaning tool blind into the switch deck.

After solder repair to the rivet, contact, pc trace interface and you still measure high resistance you can rotate the wiper so it is not between the contact fingers and then very very gently press down on the contact fingers and then rotate wiper into the gap and watch to see it strikes properly and lifts the contact finger up as it rotates in place from each direction . Then you can re-measure the resistance. Again this has to be done very carefully as easy to press it too far.

If you have gotten the bandswitch contacts out of alignment with the S22 switch in PA cage usual symptom is cant load properly as now selecting wrong tank coil tap and padder caps for a given band and maybe even have glowing final tubes.

I am not sure what will happen if you just mis-align the band switch decks. I would assume would loose RF drive and ALC indication as wrong or no Mixer and Driver tuned circuits would be selected.

If you take a good brite flashlite you can look down inside the gaps between the boards and see the white circles. Place band switch at 10 (30 meters) and look at each deck and should see all the white dots at 9 oclock (left side with rig facing you).

You can also see if you have switched on of the 4 contact boards for one of the multicontact boards.

If they are all aligned correctly and appear to be in correct order then will likely have to pull the RF board and inspect all the pin soldering under magnification.

The relay is not a sealed relay just a dust cover. No good way to remove cover and clean the contacts. Any attempt to do so has element of risk of damage and any fix you get wont be long lived.

That .01 decoupling cap is discharging to ground thru one of 8 contacts in this Aux relay. The contact in question controls switching the 6146 control grid cut off bias to operating bias by grounding the end of the bias voltage adjust pot. Very seldom a problem.

Have to study the schematic and understand what all 8 contacts do. Relay can cause no ALC indication as contacts do switch from ALC to AGC monitoring. Relay can cause delayed return to receive as mosfet Rx and Tx gate 1 bias voltage is controlled.

There are couple of people looking for replacement NF4EB aux relays at this time and they have found sources and expect them to be available again soon.

If you have rig in SSB mode and mic gain is down and flip to send or push PTT and get output power I would check carrier null adjustment first. Service manual describes how to do that. Can be done with O-scope, RF probe and VTVM or if no test gear by placing another receiver close and listening for the null. Have to perform in LSB and USB to get balance.

Also, is SSB audio clean?

Also, if note is clean with driver tube pulled then you have to be listening to the output of the TX Mixer and it means then that cause is not FM-ing due to any of the LOs varying.

By installing the Driver tube you are adding plate supply and screen supply and if they had bad filter cap could cause raspy note, but these supplies also supply finals screen grid voltage. Also adding the heater voltage and we already discussed heater to cathode leakage and heater supply bypass cap and choke. You are adding the interstage coupling capacitor from Driver tube plate to 6146 control grids and dc leakage would effect final control grid bias, but KW uses two caps in series to avoid this.

I agree study of the schematic is in order.

You could temporarily touch a good filter cap to the anode and screen grids of the Driver tube and see if note cleans up. Have to be careful doing that.

47412. Whackamole returns

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-04 13:58:22 UTC
From: <rrmvargo@...>
Topic: 47412 Message: 47412

Hello to the Group,
When I was first given the Whackamole, I did a cursory check of the major e-caps. I checked them for value & ESR. The original HV PS caps were about 120uf & 0.2ESR. Well I thought they have creeped up on value but were probably OK. But early last week & all of a sudden, it couldn't produce more than 40-60W. I noticed it would peak near 90W & drop quickly to around half that. I switched the meter to read HV & noticed it was varying ~600, down from 800+VDC. When I opened it up, I found the 2nd HV PS cap to measure open on my ESR meter & 10nF on the cap meter. The first cap still measured OK at 0.2ESR and 120uF.

I ordered 2 caps from Ken & some other junk. He shipped the day of my order, nice. I installed the new caps & HV is back up to near 900VDC on the radio's gauge. I measures 988VDC on my DVM. And the rig now puts out +100W again. And while I was in there I touched up the IF & RF board coil packs.

BTW, it has 6146W's, GE I believe. I did get an arc one time with these, after installing some of the suggested protection in TIE 004. But I have not experienced any issues since then, save the HV PS cap. Perhaps, moving the chassis around caused the tube elements to shift a bit or I knocked some debris loose in the tube.

I had the 830 on last nite & was told I sound the best I ever had. I was using an MD-100 Yaesu mic. Now I own a TS590 & FTdx3000 & IC751A. So I took that as a complement or maybe a knock on the other radios (or how I have them set up).

I love my old TS-830S. - 73 Bob W8RMV

ps- I have not checked the screen & driver caps (22uF 450V) as I have not pulled the IF board. Are they at great risk?

It's a very nicely composed, attractive and entertaining presentation. I am hoping that someday the lucky owner of the seemingly unmolested Gold Label TS-830S will turn the IF board over to see if the empty filter circuit board holes really are pristine with no sign of desoldering. Either way, it would be revealing.

Hi I have a Kenwood TS 520s and it does not have a DC to DC converter on it.
I have been looking for one for about a year now. And I have never run
across one.
I was wondering if I do run across one, can I use one from a 520, on my
520s?
and what would be a good price for one?
I know I could just get an over the counter one, but I rather have one that
would
go on the back of my radio.
Can anyone fill me in on DC to DC converters? Thanks for your time. I
just love the group here, I am learning so much....
Thanks 73

Terry K9TW

I know this sounds Stone-Age,
but I sometimes find local band conditions so very bad
that CW signals come across with the band noise : raspy.
Low end (7025) can be bad and upper end (7125) is cleaner.
Terry, your advice about the rigs is always interesting.

Yes propagation can have all kinds of effects on signal quality. Polar echo or flutter for example come to mind.

However we are talking about a raspy transmit CW note that the poster is hearing in a seperate receiver.in his shack. On occasion you can get have Fm-ing occur which will make your CW note not pure. Can also modulate it with 60hz or 120 hz due to power supply problems.

Why dont you ask Byron if gets same on air reports on all bands and at different times. If he does pretty safe bet he has a problem. I guess I assumed he had already exhausted that or thought he had said so in earlier post?

OK good. So what change occurs when you install the Driver tube?

Well you are amplifying the 2 or 3 volt Rf drive signal from the TX Mixer to the control grid of Driver tube and producing a 60 volt or so Rf signal at the anode. That is then coupled to the control grids of the 6146 finals as a 49 volt rf drive signal.

For one thing putting Driver tube back in socket introduces the anode and screen grid supplies into the mix. Are they clean?

I still am interested in if SSB TX is clean.

Terry-

I found the source of the raspy TX CW note in my TS-520SE, it was the dual 22 uFD at 450 VDC electrolytics. I went ahead and replaced both of them. The originals were not the nice ELNA brand as used in most units, they were a "Marcom" brand from factory. Even though I know it is not the best practice, for now I replaced the pair with a set of good used ELNA's from a TS-820S parts unit I picked up recently. I reformed the ELNA's on my capacitor checker and checked them, they checked out good. I installed them today and all problems went away.

I need to find a source of these dual 450 VDC caps in order to keep some spares on hand, does anyone know where they may be obtained (or, will we have to resort to stuffing or building a small PC board?).

Thanks, Byron WA5THJ

From: Byron Tatum
Topic: 45334 Message: 47425

OK Terry-
Yes, all notes sound very good up to and immediately past the second TX Mixer on RF Board. I have already replaced the 14 VDC filters (2 of 2200 uFD) and the PA Bias filters (2 of 33 uFD). All of these were the ELNA brand, which normally are very long lived and high quality, and the caps were OK and not really bad at all.
I am starting to suspect my screen or plate voltages also.
I can adjust bias to idle finals at 60 mA OK, but the finals cannot be driven past approx. 130 mA with full carrier on 75 meters, showing about 35-40 watts output. I have installed a tested, NOS 12BY7A Sylvania made from a Motorola branded box. I have not checked the GE 6146B's or substituted there yet.
Today I will focus on the 210 and 300 VDC voltages and the two dual filter caps C-15 and C-16.
Thanks, Byron

Not at great risk but I have replaced them in my personal rigs and some customers request that I replace them along with the HV caps. I have a box of 22uf Elna 350vdc pulls that ESR around .67.

When they fail usually dont cause as much collateral damage as the HV caps but I have seen burned up R11 470 ohm resistor in the C-R-C filter path and a carbon path burned under R11 on a TS530 If board where it is mounted back with the 4 caps instead of on the HV rect board. Pretty much ruins the IF board.

Ken K4EAA sells Nichicon 450vdc replacements that ESR around .90. .

Thank you Terry.

I got 4 of them from Ken also. And my measurements agree with yours 0.85 to 0.92 ESR. The original caps do not show any physical distress that I can see. So I'll leave them in there until I see an issue with them or some other issue crops up. As I was typing this I had a thought that I might be able to trace their connection & see if I can get to the leads on the topside of the board from another component. My 830 is a 2M SN, so it is on the old side compared to the 8M numbers.

My 830 sounded so good yesterday, that a fellow ham I ragchew with is pulling out his TS-520S for tonite!

I purchased three of them for my 830S and only needed one. So if someone wants one, I they can have it for $15.00 shipped. It in new not a pull. It worked well in my rig.

I also have the other relay. I forgot which one it is but it is a small black cube and I had to buy 10 to get one so I have 9 of those too. This was when I went through my 830S replacing everything that could go wrong in the future.

If you want to contact me please do it off list.

Thanks Terry,
I think you're right, I'll have to pull it apart again and do some more checking. Is an ohmmeter good enough or do you recommend another way to test those switches? I think someone mentioned checking voltage drop across the switch but not sure if that can be done while it's still mounted on the RF board.

I knew I was right!

There are several web sites that claim the 830 Gold came with all the filters. I disagreed and told those that were dead set on this point that I disagreed and why.

Here we have a NEW TS830 Gold, with only the stock SSB filter.

But I'm not gloating.

47443. TS-520 Receiver Spurious Responses

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-05 03:51:31 UTC
From: Byron
Topic: 47443 Message: 47443

Hello-
I am going through a very nice condition TS-520 (not the "S" version)and I discovered the receiver is full of spurious responses. I have never noticed this on any other TS-520 or TS-520S that I have checked out. As far as I know everything else is OK on the unit, I have checked voltages from the AVR board, gone through the RF alignment of front end coils and adjusted the receiver traps per manual. On 75 meters there are two signals about4 KHz apart, one stronger than the other; I noticed this when adjusting L-11 while tuned to a 3.736 signal. It is not as pronounced on 40 meters, but when I turn on the calib there are spurious signals all over the band, some fairly strong;enough to make it a little hard to find the actual calib signal.
I also noticed a mod someone has done: They broke the red wire going to the VFO power plug and inserted a 500 ohm pot in series with it. I measured about -2.0 VDC on VFO side of pot.
Any advice appreciated, Byron WA5THJ

47445. New TS530/TS830 Drive Control Drive Sprockets

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-05 11:37:36 UTC
From: <wagstw46@...>
Topic: 47445 Message: 47445

I have just had an opportunity to get my hands on the newly designed and manufactured upper chain drive sprockets for the TS530 and TS830 rigs. Those of you who own or work on these rigs know that the original white nylon sprockets crack at the set screw tapped holes and if bad enough can allow the three air variable capacitors to get out of sync that among other things causes the ALC indication to get touchy and RF drive to be less than ideal.

Gregory NR6C has manufactured these beautiful replacements using a 3D printing process and is now offering them for sale on his website. Go to WWW.NR6C.COM and click on the link to see the design story and place an order for your sets.

I have installed a set in one of my TS-830 radios and they work just fine. The install is easy. Just take a digital picture of the original installation. Mesh the plates fully which should bring each chain tensionsers up to within one link of engaging the sprocket teeth. Loosen the 4 screws on the brass coupler and slide it back. Now you can grasp the drive shaft with the cracked sprockets and dis-engage it from its bearing stanchions on each end. Now you can remove the chains and the old sprockets (assuming previous owner didnt attempt JB Weld or Epoxy repairs). Use a jewelers file and clean the burrs off the shaft where the old set screws seated. You can also lightly polish the shaft with crocus cloth or fine sandpaper. Now just slip on three new sprockets and reverse the assembly. Make sure that all plates are fully meshed and when you move the Drive control knob that they all open simultaneously. They may not if someone has stretched out the chain tensioners. With the knob at 1200 position all three capacitors should be 50% open.

I want to thank Gregory for his efforts. When I hold these in my hand it is hard to believe how quickly from the idea to actual production this has happened. In my day the draftsman would still be sitting at his drafting board working on the hand drawn engineering drawing.

Check with Greg regards availability and shipping. He has set the price very reasonable. Looks to me like it is just a labor of love to help our members keep these treasures on the air without resorting to bubble gum and baling wire!

Topic: 46900 Message: 47446

Dave:

You can try measuring in circuit, but I dont think you will be successful as too many shunt paths.

I dont know if you used good lite and magnifier or not when you did this. For me it is a must. I wear a magnified head set.

You have to make sure that the rivet head, contact material, and the PC trace are cleaned very brite to remove all oxide and solder mask. On some contacts you have very little trace to work with. You really only need to electrically bond the contact material and the PC trace but due to small size and spacing pretty much have to get the solder to flow and wet to all three materials. Also by engaging the rivet head it prevents it from rotating back and forth. You just need to make sure that you have not just bonded the rivet head and the PC trace and not got good bond to the contact material.

For this reason I still lean toward the installation of a very small gauge tinned bus wire (I use #26 to # 28) from the window of the hair pin loop to the PC trace. This may not completely limit rivet rotation, but you no longer rely on the rivet pressure for the conductive path.

As to contact resistance a DMM, or ESR bridge is commonly used and depending on your lead resistance should be able to get all to close to 0.10 ohms.

A better test would be the standard relay contact "6/1" test where you apply 6vdc from a bench supply or lantern batteries limited to 1 ampere thru a series resistor or pot. Then with your DMM you measure the IR drop across the contacts. Should read better than 100mv across each contact. 100 mv IR drop across the contact = 100 milliohms.

I only suggested that you fold over the the audio board and remove access plate so you could look at the pin soldering to make sure you didnt miss any or have bad solder connection at that point. Up to you if you want to start there.

Probably at this point you are going to have to pull the board again. If you do that just remove one bandswitch deck at a time. Have to be very careful now not to lift pads during 2nd unsolder/resolder cycle. No need to bend the two tabs over when you re-install.

I have to say this is not an easy task but also not beyond average hams ability. I have however seen some attempts that looked like a pigeon may have flown over head and left a deposit at the contacts. Very easy to just blob on lots of solder.

Lastly, dont be tempted to press around on the contact fingers. If you do that without the wiper in the gap between them you can press them down in the opening as they are very soft and really have very little spring temper. If pressed down too far then when the wiper passes by it may catch the fingers and bend the contact aside and now you are really in trouble. Almost impossible to get back in alignment. I seldom see a bad contact due to not enough pressure between the mating fingers. When I am done I rotate the wiper back and

forth thru the contact and watch it strike the bent up "wings" on each edge and lift the contact as it slides thru. If you see this lift of the upper contact finger you know you have adequate contact pressure.

Sorry so long. Just trying to share what I know and if you read thru the lines might be able to figure out that I have learned the hard way.

Terry K9TW

Byron:

I have written on this more than once and not sure if easy to pull it out of the archives or not in this new format. So will share some of it again.

You should also find a strong birdy at 21.20. These birdies are inherent in the design with the 3.736 the most objectionable. It is due to the mixing scheme and LOs used. The Het LO at 12.395mhz is the biggest offender.

Kenwood talks about this when they introduced the TS510. Look at the owners manual on page 10 Section 8 and you will see they discuss "spurs" even listing the frequency of the biggest offenders. The design and mixing scheme of the TS520 is the same.

If you look at the TS520S you can see how they minimized this problem by placing a suck out (series resonant) trap T13/C62 at input of the Mixer Q9 on the IF board. RIF mixes with VFO here and it sees the 12.395 Het LO leak thru.

If you look at the TS520 you will see that trap L2/C15 is placed at the output of Q4 Mixer where it is less effective. I pulled a L2/C15 from a parts 520 rig and tack soldered it at TP-2 on the IF board and could then alternately adjust both traps to pretty much completely null the 3.736 birdy. it is still installed on my personal TS520.

Some members report they dont hear these birdies or never noticed any of them. Some folks have a less discriminating ear and/or these are rigs that have not been well aligned or have aged and never been given a tune up. It is a design flaw that among other things the TS520S changes addressed.

One other thing you can do is try lowering the 12.395mhz Het Osc level. Typical for it to be peaked at approx 800mv to 1.0 volt. If you lower it to approx 600mv level at TP-3 the audio level of the 3.736 birdy will be greatly reduced and the S-meter will fall back to zero.

600mv should be enough Het Level for good Rx and TX mixing. Just have to make sure Het Osc starts reliably each time you switch to 80 meters.

Byron

I forgot to mention if you dont like the idea of reducing the 12.395mhz Het level to 600mv and want to mod the rig to match closer to the TS520S improved design and have no access to a scrap RF board to pull the series resonant trap you can just make your own trap.

If you calculate the LC values for 12.395mhz you will see you will need a 5pf cap and a 28 to 30 uhy choke. Want to stick to this approx LC ratio for adequate Q. The actual values wont exactly match what you calculate because when you tack in place at TP-2 there will be circuit parasitic capacitance and inductance that will effect your trap Fc. Best to use a miniature tuned slug inductor of from approx 26uhy to 30uhy if you can find a nice small one. Might try Surplus of Nebraska.

I would try reducing Het level on 12.395mhz to around 600mv as a first step that may make the birdie level tolerable for you.

You could also contact Bob Mansker and see if he has a parts TS520 RF board. More expensive option, but then have a plethora of parts.

Thanks

Way over my head. I am no relay engineer.

I worked with relays of all types for years in fossil and nuclear power and in fossil plants not too many relays with silver contacts due to hydrogen sulfide atmosphere. I didnt spec them. I caled and tested them under PM umbrella and replaced them under CM. Had to be very careful as some were in CT circuits and if opened could be fatal. Most were on a 5 year cal frequency. Dont remember too many with bad contacts.

We did have a lot of high ampacity bus work with bus splice plates or 'links" as they were called and I remember using a product called Cool Amp which was a white powder and you dipped moistened rag in it and rubbed it on the surface of the links. It actually deposited thin coat of silver. Was very expensive. Dont know if it still exists or not. Might be some application for it in our rigs? Maybe apply it to the band switch wipers? Hadnt thought of that until this point paper.

I am just telling people that OK to use ohm meter to measure contacts for gross indication, but the standard "6-1" test described in almost all manufacturers relay app notes is better measure of contact resistance. Most hams dont own a Milliohm meter as they are expensive so measuring the millivolt IR drop is easy for them to do as most have a DMM and if dont have a DC bench supply 6 volt lantern batteries are good alternative.

Thanks for sharing.

47454. TS-530S SSB filter adjustment

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-05 17:26:53 UTC
From: <crgrbrts@...>
Topic: 47454 Message: 47454

I am revisiting this topic with a different query.

To recap: I recently replaced my TS-530S's 2.4 KHz SSB filter with an 8-pole 2.8 KHz INRAD model and I am attempting to optimize the SSB frequency response (Step 24 in the ambitious TS-530S alignment sequence).

When last we spoke, I did not have an AF tone generator at hand. Well, now I do -- kinda. It's a software driven tone generator downloaded from NCH Software (http://www.nch.com.au/tonegen/index.html). I can inject its tones into my radio's mic jack via my SignaLink digital modes interface. It seems to work nicely. I can set the generator to any frequency or series of frequencies I wish. However, given my lack of test gear, I have no way of regulating its output to the specified 7 mV level. Does this matter much?

If not, here's my cunning plan: I will tune the radio to 14.175 MHz USB as specified, inject a 1500 Hz AF signal into the mic jack, and tune up the transmitter to 50 watts output into a dummy load as measured by my trusty and newly calibrated Drake W-4 wattmeter, I will then inject tones at 300 and 2700 Hz alternately and adjust the appropriate trimmer (TC3) to obtain equal output drop offs at the two frequency extremes. Then, switching to LSB, I will repeat the process by adjusting TC2.

Does this sound feasible? My TS-830S transmit audio is easy to tailor by ear by employing the radio's built-in monitor. The 530 is a bit trickier to do by ear, however, since a second receiver, with its own quirks, must be used.

On air tests with other hams aren't always reliable. Not only does propagation and the status of the correspondent's receiver influence audio reports, the personality of the guy at the other end is a variable. This is otherwise known as the W2XXX vs. W5XXX principle (just kidding -- sorta).

Whaddya think?

73,

Craig
W3CRR

47456. TS-520 Confusion Over Resistors between RLT and TBL Terminals

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-05 17:07:47 UTC
From: Byron
Topic: 47456 Message: 47456

Hello-
Possibly someone can shed some light on this for me. I was going through a TS-520 and found what appears to be a mod. There is a small terminal strip mounted along the edge of the IF board that has a 4.7K variable resistor in parallel with a 4.7K fixed resistor, and these in series with a 2.2K resistor. One end of this combo goes (blue wire) to the terminal TBL on IF deck. The other end goes (red wire) to terminal RLT on the RF board. It appears this is a mod added as the red wire connected to RLT on RF board is soldered instead of wire wrapped. However, the blue from combo is wire-wrapped like factory at terminal TBL on IF board. Plus, there is another factory appearing blue wire that goes from TBL on IF board to TBL on RF board. Although this combo that was added appears as a mod, it is necessary in order to transmit. What confuses me is that some TS-520 schematics show this "mod" and have part numbers assigned to the resistors (R-20, R-21 and VR-11). I have looked at several parts units IF board I have here and some have two blue wires at TBL and one only has one wire at TBL. Since my IF board has two blue wires that appear factory installed at TBL I am wondering where the second blue wire originally went?
Thank you, Byron WA5THJ

A newbie question, where and how do you find the date code on the tubes? Is it truly a code(the small dots) on the glass or the numbers like 188 5 (yes there is a space) on mine? Thanks for any replies.

Jerry K4GEW
Just checked 4-6146w's I have put back for my TS-820's. To the right of the name label on the tube is a number. On one pair it's written horizontally, one the other it is vertical. Both sets match closely the *boxed*date stamped on the box, ie: 2-79. There is much info on internet about the 6146, 6146A,6146B, 6146W, 8298 as to quality, specs, date of manufacture changes, on so on. Hope this helps.

47465. Meter pegged in IP on transmit on TS-830

Yahoo group: TS-520_820_530_830 (2014)

From: <paw_paw44036@...>
Topic: 47465 Message: 47465

Terry,
I am a bit confused here. I had my 830 working fine today and all of a sudden the IP meter pegged on transmit.
My confusion is that I have three different manuals and on the RF board, one shows R-10 as a 10 K another shows it as 6.8K and another shows it as 4.7K
Ken’s big schematic shows 4.7K. This resistor was cracked and I can’t see the first band. I assume that is what made the meter peg as it checks 55k ohm.
Also while I have it apart, I am going to add the transformer saver circuit. I assume the resistors go in series and in series with the 900 volt line. Is this correct?

I see R10 (on RF board) as a 470k.
Check your four cathode resistors, I have seen them all blow and the IP needle goes pegged.
I did the glitch resistor mod, and yes the two 4.7 2W resistors are in series, AFTER the filter caps, just like in the Hybrid Tech article picture.

Bill;

Bill anytime you have an arc over the meter will peg violently as you have 900vdc IR drop across the cathode resistors. This is a meter designed to measure 1.75vdc so imagine applying 900 vdc across it. Actually across it and its series meter multiplier but none the less one hell of a lot of voltage for a moment. R10 wont stop that. It is there to address the jeopardy to the meter after the cathode resistors have blown open.

R10 was a mod by Kenwood to hold the cathode down to ground potential after and arc over event. In the event of a tube arc over and cathode resistors popping open you now have and open cathode and the cathode will try to rise toward Screen grid potential. It will quickly climb to well over 100 vdc (I have measured it). Now with an open cathode after an arc over event and you try to load again and you flip the panel meter selection switch to the IP position you are applying very high voltage across the meter and will peg again and can burn it out. R10 assures that the cathodes of the 6146 finals stay at ground potential after the meter shunts pop open.

Depending on what serial number rig you have it will be a 4.7k to 6.8k ohm resistor. The value is not critical as it only makes about a half a needles width of difference in meter deflection accuracy. It is not the meter multiplier and has nothing to do with using a ua meter movement as a voltmeter. I recommend people put in the value that matches the schematic revision they are using so not confusing if need to troubleshoot. Actually can take R10 out and throw over your shoulder and meter circuit will work just fine.

As I said I have measured the cathode with all the cathode resistors removed and it will rise quickly to over 100 vdc. If R10 is in the circuit you will get no cathode potential rise. There is no equivalent of R10 in the other KW hybrid meter circuit just the series meter multiplier.

If you are going to do any of my protection mods I recommend the 3 diodes in series to protect the meter by limiting the IR drop across the cathode meter shunt resistors to approx 2.1vdc in a fault event. Meter will still peg during the event but not violently.

The only reason I placed the two Type OY glitch resistors in series was because I could not find a single 10 ohm resistor designed for surge current. If we had 3000vdc anode potential then I would have used several resistors in series to spread the leakage path. You can use two 4.7 or 5.6 ohm resistors in series. These are commonly available values. The value is not critical. Just trying to add some impedance in addition to the 5 ohms and whatever the transformer ESR is to limit the fault current. With just 5 ohms you could have 900/5 = 180 amps at moment of the arc over.

We do not want the glitch resistor to pop open (it is not intended to be a fuse) and interrupt the anode voltage. Never want screen grid voltage applied and no anode voltage as screen grid dissipation will be exceeded and tubes destroyed.

The installation of the MOVs is optional as not likely to arc from anode to screen grids. Closest element is the beam forming plate or suppressor which is tied to the cathode so

normal path is from anode to cathode. Is possible to arc to the SG so I added the MOVs.

R10 is on the Final Board of the TS530 and TS830. A KW redesign of the meter circuit in a feeble attempt to protect the meter. Correct fix is to never allow cathode meter shunts to open. The transformer primary is fused.

Jerry

Good question and it is very common for one of the chains to be more loose than the others. I have actually places small shim over the drive shaft to raise the shaft out of the saddle of the insulating stanchion and increase the spring tension. I have done that by slipping on a thin plastic bushing or a thin metal bushing over the end of the shaft. Easiest to slip a shim at the output end of the shaft (nearest the PA cage) as the inboard end is coupled. Puts a little angle on the shaft but not a problem.

Only other thing I can suggest is to try to squeeze both sides of the spring wire tensioner device to close up the gap and provide more spring tension. Have to do that with the chains off the sprockets.

If I had to have any chain loose and cause some lag in plate movement it would be on VC-1. I would put my best chains on VC-2 and VC-3 (middle and nearest PA cage) so that the Mixer and Drive coils would be tuned to resonance at same point. This helps ALC indication in Tune mode during rig loading to be less touchy. I dont like for ALC indication to sort of pop in and out or have to go past it and come back to peak it. Prefer more smooth peaking action.

May come a time when will have to come up with miniature springs to replace these tensioners. Whatever you do....do not apply any heat to them. You could heat the spring coil on each side and quench to re-temper but I would be prepared to have to replace.

Easy! I applied my software derived audio generator through my computer soundcard and into my hybrids' mic inputs this evening and it worked a treat.

The 2.4 KHz SSB filter in my 830S and new 2.8 KHz INRAD device in the 530S are now set for best and balanced audio response. I am getting very complimentary on-air transit audio reports to confirm the measurements. (The receiver sounds nice, too).

The point is that I have learned that a $30 piece of software (yes, I actually paid for it) can do the job -- in this case -- of an full fledged, standalone audio generator. I couldn't imagine why this computer aided tool wouldn't work, but it's nice to see it in action.

Joe et al:

Yes Gregory deserves all the recognition and our thanks. My role was to just provide a set of original parts that were not cracked and to try the finished product.

In interest of full disclosure I need to say that during the installation and testing I did notice that the chain link had a tendency to snap into the gap at the base of the adjacent teeth as the Drive control is rotated.

When you turn the Drive control knob you can hear and feel this engagement occurring. It in no way affects the ability to peak the ALC indication in receive or transmit. It may become less noticeable as the chain and new sprockets run in with more use. I suspect that it will and depending on the condition of your chain may not occur at all.

I wanted to mention it so no surprises to anyone who buys and installs the new sprockets. I suspect not ever having the opportunity to operate a brand new TS530 or TS830 and only having adjusted the Drive control of those radios that had many rotation cycles on the Drive control that I may be a poor judge of what new and "normal" feel may be.

I am a very happy camper with my new sprockets. May leave the covers off for awhile just to admire them!

Yes this is the precise method that all the KW hybrid service manuals describe.

All you need to know is that the millivolt level at 1200hz to 1500 hz where you set the mic gain for 50 watts output does not vary at all at 300hz and 2700hz because if it does then you have no idea if the 25 watts or where ever the roll off is at is due to the filter response curve or the fact that the generator level is dropping.

My guess is that the mv level is just as accurate as the frequency is. Cant buy a good AF generator for what you invested in that software and I suspect it also gives you 2 tone testing capability which your typical budget AF generator wont. Lastly, you can use it to adjust your VBT oscillator if it has capability of two output channels that can be mixed. If not there is other audio generator software out there that has two output channels.

Terrific, Jan! I love your website. We have several common interests, but we can chat about them in Dayton.

So, who else is going to Dayton? I'll be there helping to man The American Legion Amateur Radio Club booth (our first time at the big hamfest). My hybrids get a workout doing net control duty for our club once a month.
Our next HF net is this coming Sunday, Feb. 9 -- 7.238 MHz @ 2200 UTC, just following our friend Mark, WB0IQK, and his Drake Technical Net buds (including me).

Stop by and say hello!

73,

Craig

Hi Scott,

Well, here's what I did:

I purchased, downloaded and installed the NCH Tone Generator software (http://www.nch.com.au/tonegen/). I am not endorsing this particular program, but it suits my needs for radio alignment use plus some other purposes. (I have a small voiceover and narration studio in my home, cohabiting with my radios). As Terry suggested, this program does, indeed, offer sweep tones, simultaneous generation of two or more tones and other useful functions

From the software's setup menu, I configured the NCH Tone Generator to feed the Kenwood's mic jack from one of my computer's USB ports through a SignaLink USB interface. This device has a built-in sound card and allows control of its output level. I could also have connected the radio through my W2IHY iBox from my computer sound card (a trusty old M-audio Delta 44) or directly -- as you suggest -- from the computer speaker jack. I just figured the interfaces would provide a little isolation and a cleaner tone.

For the filter alignment itself, I simply followed the instructions in the TS-530S service manual (Step 24) using my Drake W-4 wattmeter as an output indicator. I tuned the radio up to full output into a dummy load, then switched it to USB mode, injected a 1500 Hz tone and reduced the output to 50 watts. I then switched the tone generator to 300 Hz and checked the output and did the same with a 2700 Hz tone. Alternating the two tones and tweaking the appropriate trimmer, the filter was easily adjusted for equal fall off on both high and low tones. The process was repeated in LSB mode. The whole process took just a few minutes and was quite easy.

In the case of the TS-530S and its new 2.8 KHz SSB filter, the output at 300 Hz and 2700 Hz in both USB and LSB modes was about 23 watts -- a near textbook -3 dB from the original 50 watt at 1500 Hz level.

The proof, of course, is how the transmit audio sounds and, according to a couple of listeners, anyway, the adjustment worked just fine.

I also re-aligned the stock 2.4 KHz SSB filter on my TS-830S. Before alignment, it was pretty good on USB, but LSB was way off with almost no attenuation on the low end (300 Hz) and a great deal of drop off on the high, 2700 Hz side. This explained the reports of "bassy" or "heavy" audio that I had been getting on 40 meters (LSB) as opposed to the good audio reports I usually got on 20 (USB). Adjustment, again, was simple and quick and my USB audio reports should be more flattering now.

Speaking of oscilloscopes, my ancient Navy surplus model is just not up to the job. What I want now is a nifty new PC Oscilloscope! (http://www.picotech.com/oscilloscope.html)

There has been some concerns/requests/comments about whether a 6146B sold under the "Motorola" name is any good. First, I do not believe Motorola manufactured 6146Bs. I suspect the 6146B were manufactured by another source then sold under the Motorola name. Consider 6146Bs being sold under the RCA and GE names. Do you think RCA 6146B are any better than GE 6146B, or vice verse? I don't think so so why worry whether a 6146B sold under the Motorola name is any worse or better than a 6146B sold under the RCA or GE names?

There is nothing magic about 50 watts. You just want to use a low level RF output as you have to have the rig keyed for awhile to make the trimmer adjustments. 50 watts results in about 1/2 IP current during the key down period so not stressing the finals and having to worry about key down for more than couple of seconds. You cant lollygag around but have time to make the adjustments. 50 watts is also easy to remember your starting point and to know that when power has dropped to approx 25 watts you are close to 3dB roll off. Depending on the response curve of your particular filter may or may not be 25 watts.

Now you need to download free copy of Spectrogram and feed the head phone jack output into your lap top line or mic input and actually see the results of your good work!

It is great fun.

Like I said, I was confused and your right, it is the final board. My mistake. Sorry. I took a chance and put in a 6.8 as it was in the middle of the range of the three schematics. Everything seems to be working ok. Cathode resistors check 5.3 ohm. The only resistor that was high was R10. Just for the heck of it, is there away to use a DVM to check the current and to verify that the meter is telling me what is really there? It loads up fine at 100 watts on all bands except 10 meters which is 85 watts. But the meter reads 275 ma at full load and will not dip below that without losing power output. if I back the drive down to 225 ma it only outputs 75 watts on my Bird 43 meter. I question the meters accuracy. I see on the AF unit that there is a cap and resistor tied to the relay and meter and a cap across the meter. If anyone of these fail, could it render the meter inaccurate? Bill WD8OSJ Serial # 3080247 built in 1982. Gold label.

Important thing about the 50 watts is you want to
make sure the AGC has not active. If it is, you
need to lower the 50 watts to a lower setting so
the AGC is not having an effect and skewing the results.

You know what would really be great is if someone
arranged to have a Kenwood forum at Dayton, say in 2015.

I'm part of the group that puts together the
Drake forum and we always have a full house,
which is typically 100+. Last year we estimated
it was maybe 125. Wouldn't it be great to get
something going for the Kenwood Hybrid guys?

Volunteers?

I think you mean ALC and I would rather have full ALC indication so I know the ALC bus voltage is being pulled down to a constant level.

You are correct you sure dont want the TIF amp output to be varying while you are varying AF sig gen output frequency.

At 50 watts you can be pretty assured that the ALC bus voltage will be pulled down from 3.6vdc (RF-1 level) to around 2.3vdc to 2.6vdc. Need a high Z meter like a HP-410C to measure it. I have looked at it during this test and and it doesnt vary as you go from 300hz to 2700hz. This is why the procedure in the Service Manual doesnt mention anything about ALC control bus voltage must remain constant. They assure that by using high enough output power level.

There is one thing you could do if concerned about any ALC action and that is apply 3vdc from couple of flashlite batteries to the ALC molex pin connector. This would be a low Z power supply and would set the TIF amp gain regardless of what the ALC Hi-Z power supply does.

So Mark your are correct more than one reason to use approx 50 watts. Less stress on Finals and to be assured that ALC bus voltage isnt varying which would vary the rf drive and output power level.

If anyone wants to set the Carrier point using this method just follow the Service Manual steps as written and you will be just fine assuming you have a good stable AF sig gen.

I've replied to Craig, off line, about the 2.8khz
filter verses the 2.4khz stock filter when it
comes to adjusting the tones per step #24 in the manual.

I think that procedure needs to be slightly
modified to take advantage of the wider filter.

The higher the cathode resistors go the meter will read the IP current false high. This is a conservative failure.

Yes you can read the voltage drop across the cathode resistors with your DMM. The accuracy of the meter is also dependent on the series meter multiplier resistor. You can use a 1% there but kind of silly as can only read reasonably accurate to half a meter division. The resistor to measure is R6 2.7k. It seldom is a problem. It is a 5% unit.

The way this works is you are using a 500 ua meter movement and adding a series multiplier and converting it into a voltmeter (same as what is going on inside your VTVM or VOM) to read IR drop across the cathode meter shunt resistors.

This meter is a 500ua movement with 800 ohms internal resistance. This means full scale deflection is E = IR or E= 500ua x 800 = 0.40vdc for full scale deflection. To make it read higher voltage you need to place a resistor in series with it to drop any voltage greater than .4vdc across.

At 350ma the drop across the cathode resistors is E= .350 x 5 = 1.75vdc. So with the meter on Ip and reading FSD there is 1.75vdc from cathode to ground.

This means .4vdc across the meter and 500ua flowing thru the meter movement and the R6 series multiplier. 1.35vdc will be dropped across R6.

At 225ma there will be E = .225 x 5 = 1.125vdc dropped across the cathode resistors.

The capacitor and resistor you are talking about is to address the meter damping or dampening. All meter movements have "ballistic" characteristics. You dont want the needle to overshoot, oscillate, or flutter at the indicating point. You want it to settle there pretty quickly.

They do employ various forms of mechanical dampening. However , what KW did was use a RC circuit to to electrically dampen the movement. The moving coil actually acts like a mini-generator so adding external RC time constant can dampen the movement overshoot oscillation time constant. I doubt anything wrong with that circuit. The cap across the meter is an Rf bypass.

Just check R6 and make sure it is close to 2.7k ohms.

You simply run the AF generator frequency up and down to see where the 3 db roll off for a given filter is at and adjust the trimmers to where you want to place the Carrier Osc at. Some prefer to set it for more Bass and some for more Treble and some split the difference. You are not locked at stopping at 300hz and 2700hz or 400hz and 2600hz as noted in the service manual. The wattmeter will tell you where the roll off is at.

You can make a chart for your filter and even graph the response curve. I have done that by swinging the AF gen from approx 50hz to 4khz. At approx 50hz and 3300hz no rf output. At -12dB I see approx 170hz and 2850hz with a YK88-S1 installed.

Of course when done you still have to decide if it sounds good to your ear. I prefer more communications audio and not the classic KW bass audio so I adjust the trimmers for more highs presence. Running barefoot and chasing some DX I think it helps me.

Would you envision it being a Q&A session or some power point presentations or both?

Maybe get Jan to give presentation on SDR and L-pan interface with KW hybrids? Maybe Dick present band switch repair?

Might be interesting if could demonstrate how to load a KW hybrid. Lots of confusion and voodoo stuff going on there, but not sure how would project that so all could see.

I would participate in a Q & A panel. Some risk of speaking from memory. Nice to have the reference documents at the ready. I suppose could access on line via lap top or bring hard copy.

Mike W5RKL

What is the criteria for determining if a 6146 is 'good' or not or somewhere in-between.
Is it the ability to perform at 100% EPO ?

I cranked the TS830 up to 150W EPO , mode CW, measured on my Ant Tuner, one time.
The only way I could determine if that usage would work in the long run
is by a method known as "Destructive Testing", ie, run it until it fails !

I am suggesting that
there should be some other method of determining if a 6146 is 'good' or what.

I am NOT suggesting that Knwd users run their rigs
at 5 W normal and 10 W in noise.

I am suggesting that Knwd users run their rigs
at 60 %, aprox. 100 W normally.

Using these requirements, 'any' 6146 should last a long time.

Comments ?

Terry,
The 2.7 ohm checks at 2.69 ohm on my Fluke 27 meter. At 5% I would say that is good. The four cathode resistors check 5.6 ohms so I would say they are ok. The only resistor I found high was the R 10 at 55 k ohm.
I replaced it with a 6.8 k and all seems to be working. I clipped a 10k pot across R-10 and I can vary the meter reading by 65 ma reading It seems that this is a voltage divider circuit. I will tune it up again and set the IP reading for 225ma and see what the voltage is. This should tell me if it is accurate using your figures.
Bill WD8OSJ.

Glen,

I doubt hams have the equipment to accurately test vacuum tubes and provide an accurate answer to your question. A tube tester won't provide an accurate answer either.

If you ran your 6146s up to 150 watts "output" you were over stressing the KW power supplies. The KW hybrid final amplifier and power supplies are not designed for power output levels that high. I also suspect the 6146 screen current most likely had exceeded it's maximum rating of 12ma per tube at that power level, not a good thing to do.

The typical maximum efficiency of the KW hybrid's Class AB1 final amplifier is 60% which for the 830, for example, which has a 180 watt DC input power rating, the 830's typical output power will be 108 watts (180 x .6 = 108) when not pushed for those few extra useless watts output.

The "typical" RCA and GE recommended maximum Plate and Screen voltages and current specifications for 6146B operating in ICAS Class AB1 RF amplifier, are:

Plate voltage = 750VDC
Screen voltage = 250VDC
Plate current = 220ma
Screen dissipation = 3 watts or 12ma each tube (3 / 250 = .012)

KW runs their Plate voltage to the 6146Bs a bit higher, approximately 175VDC higher than the RCA and GE recommended maximum rated plate voltage specifications.

Heathkit designed their ICAS Class AB1 6146 based final amplifiers with plate voltages of approximately +820VDC from their HP/PS 23 power supplies. My SB-100 which has a pair of 6146As, when tuned up into a 50 ohm dummy load for maximum input power, the grid current is at 2.5ma per tube (5ma total),)grid current remains stable), and plate current is at approximately 225ma with 730VDC plate voltage which equates to approximately 165 watts DC input and approximately 98.5 watts "output" (60% efficiency) to the antenna/tuner. No need to push for more power, 98 watts is more than enough to work anyone I can hear. I work into Japan with a simple 40 meter inverted vee up 25 feet and 98 watts output. I have an AL-811 (3 tube version) but I don't use it that often, don't need it.

47501. Re: [TS-520_820_530_830] Meter pegged in IP on transmit on TS-830

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-06 17:07:49 UTC
From: <wagstw46@...>
Topic: 47465 Message: 47501

Well of course it did. You cant do that!

You cannot clip a 10k pot across R10 and not effect the meter accuracy.

You dont understand what R10 does. R10 is in parallel with the 5 ohm cathode resistors and there to take their place when/if they pop open. It is not a calibration divider resistor. The value of R10 was selected to give a low enough impedance to ground to prevent the cathode from rising toward screen grid potential. If its value is too high it will be less effective for that function. If its value is too low it lowers the value of the 5 ohm cathode resistors affecting the accuracy of the meter as you found out by applying low value pot across it.

R10 is in series with the meter multiplier R6 and in parallel with the cathode resistors when you move the panel meter switch off the IP position. The combo of R6 and R10 in series to ground keeps cathode voltage low and not rising toward SG voltage.

This is simple ohms law for parallel resistors. 5 ohms in parallel with 4.7k + 2.7 ohms = 5 x 7400 / 7405 = 4.9966 ohms. So you see adding a 4.7k resistor in shunt with the cathode resistors has virtually no effect on Ip accuracy.

The minute you place a low value pot across R10 and lower the resistance that is in parallel with those cathode resistors of course you will vary the Ip meter indication. It is simple ohms law.

Always better if R10 fails high in value as Ip will remain accurate. Just wont have meter protection if cathode resistors fails open and you dont have the meter in the Ip position to keep it pulled down thru the meter. If the meter is left in the IP position after an arc over event then cathode will not rise toward screen grid voltage as meter movement 800 ohms will hold it down (actually 3500 ohms from 800 ohms plus R6) . However it could be in ALC or maybe RF position when the event occurs. At that time you will have greater than 100vdc on the cathode and the moment you switch back to IP position your meter isnt going to like it assuming it survived the initial arc over event. So challenge for KW engineer is what value resistor to keep cathode potential rise low while not affecting meter accuracy.

You are not the first person who thinks R10 is involved and required to calibrate the meter. As I said go look at the other meter circuits and you will see a meter multiplier and no R10. As I have said the reason you see different R10 values is KW was trying to get as low an impedance as it could to hold the cathode voltage down without adversely affecting the accuracy of the panel meter by lowering the combined value of it and the cathode resistors much below 5 ohms.

If you want to bread board this take four 20 ohm resistors and place in parallel and then take a 1 meg pot and place across them and then vary the pot and monitor the 5.00 ohms and see how low you can go on the pot before the 5.00 ohms is lowered. There are some old rules of thumb for paralleling resistors. Some say 20x but that is too low a ratio for this application. I think 1000x would be OK as that results in 4.975 ohms. KW messed around and ended up with approx 1500x ratio.

By the way if you install the 3 series diodes and clamp the cathode potential rise to approx 2.1vdc then you can throw R10 away and not have to worry about blowing cathode resistors and switching the meter back to Ip position and closing in on 100vdc plus. I leave R10 after installing the diode protection to keep the rig to factory config, even though it now serves no function.

Mike is of course correct. I have only seen one or two KW hybrids that could produce 150 watt output and those had mods to the Screen grid voltage.

I realize you said "just one time" But as Mike states not a good thing to do to the tubes or the power supply.

If your rig is stock I suspect your wattmeter is not accurate.

If watt meter is accurate you may want to open up PA cage and take a look at your main RF plate choke to make sure it is not discolored and if you feel comfortable load into dummy load and measure your Screen Grid voltage.

100 watts output into good antenna and can work the world as Mikes operating experience confirms. Remember for a full S-unit on the receiving end you need to increase output power 4X.

Short key down times, loading to no more than the max Ip that is listed in your particular manual, and not running high duty cycle modes without reducing IP accordingly should result in many years of final tube life.

I forgot to mention I like to rotate spare 6146 finals in and out from time to time. In my experience letting 30 plus year old finals sit on the shelf expecting that they will be viable spares when you have to reach for them has not been a good experience for me.

That's what I suspected. I think a month or so ago it was mentioned that there were once 2 or 3 tube factories (factories in America?) that were making tubes for several brand names. Not having seen or heard of ANY Motorola 6146 tubes I had reservations about purchasing an unknown product with no known history.
Thanks for that observation Mike.
I'm trying to keep to something that doesn't resemble a budget, needing a quantity of 6146 I've been shopping around.
Buying test gear, busted radios and parts for those is keeping me busted so I'm always looking for a bargain.
Like relays for $7.50 instead of $43 or even $70!!
Have a super day Gentlemen, stay on the warm side of the door!

I don't believe my question from days ago has been answered by anyone.
If so, sorry, mighta missed it.

I asked if anyone has any experience with Motorola 6146, I think he said B's.
Found a few for not too much $$ but have no knowledge of those.

Any one have any idea of their value? Any good in our rigs?

Any experience at all? Rumors, propaganda even.....
Need to pick up some tubes quick. Price is right and they are going quick.
Thanks!

I understand what you are saying. Just seems funny that that was the only resistor that was out of value and after changing it things return to normal so to say. Only thing now is that to max power peaks at 275 ma at 110 watts out on 14,175. I was before this happened always around 230 -235 ma before it pegged the meter. I added all the mods you showed in the 3 pictures and I will put it back inline tomorrow to see what happens.

Bill

The higher that R10 goes the less effect it has on the parallel combinaton. So if R10 was at 55k ohm then it should not have affected your IP accuracy. Very unusual for R10 to go high in value. I think you said that R6 is within tolerance and was not changed out. I hope that the meter movement hasnt been hurt.

Lets review.

1. You measured cathode resistors at 5.0 ohms or very close to that with R10 removed. The cathode resistors did not pop open. Only thing that occurred is the meter pegged. Did it peg while switched to the Ip position? Sometimes it will peg because you have lost operating bias to the control grids. If you lose operating bias momentarily the meter will peg violently. Were you trying to set the resting plate current or had you just done that? Can you still set the resting plate current to 60ma?

2. You measured R6 at 2.7k ohm or very close to that.

3. You have now installed a 4.7k ohm R10. So if you read from cathode to chassis ground do you read something just under 5 ohms? Should read lower than what you read in Step 1 above.

4. If so then you know the cathode meter shunt portion is good and to spec. So what else is in the circuit?You have the meter switch contact resistance, the internal resistance of the meter (approx 800 ohms and do not try to measure it with an ohmmeter). If you have a good variable low voltage dc source that you can control its output voltage up to 0.40vdc you can connect it across the meter and see if it deflects to 350ma. You can clip on to the black and red meter terminals at rear of meter and apply 0.40vdc. Just have to be damn careful if your voltage adjust is touchy and possible to jump from 0.40vdc to a high dc voltage easily.

5. As I mentioned you have the contacts of the meter selection switch and they dont often go bad. You have the contacts of the Flat Pack RL-1 and they do go high. You have the contacts of the molex pin interface at Connector 7 on AF board.

6. With the rig down powered if you measure from Cathode pin of 6146 tube socket what resistance do you have now?

Tell me again what you were doing when the meter pegged.

Terry K9TW

47508. Re: [TS-520_820_530_830] Meter pegged in IP on transmit on TS-830

Yahoo group: TS-520_820_530_830 (2014)

Topic: 47465 Message: 47508

I made a video that discusses series/parallel resistance circuits. The serious/parallel circuit in the video is very simple and similar to the 830 metering circuit except the source voltage is 12VDC and the resistor values are different. The video can be found at the following link:

http://www.n6wk.com/w5rkl/Basic%20Ohms%20Law/Series%20Parallel%20resistors.wmv

You can change the source voltage to equal what ever the cathode voltage is. Next you change the values of R1 to 2.7K, R2 to either 4.7K or 6.8K, and R3 to the meter resistance which is approximately 800 ohms. The cathode resistors are assumed to be 5 ohms. The rest follows the video.

Perform the calculation twice, once with R2 of 4.7K then again with R2 of 6.8K to see the differences based on different values of R2.

Lap tops is included in each room with access to the outside world if needed.

For reference, our Drake forum does not need to
use wifi and I simply rely on power point presentation.

I think all those suggestions Terry made are
great. The Q&A session has alway been good and
can occupy by itself 15+ minutes. Maybe Jan is
even a member of the Dayton group and could be
the front man to get us a spot? What say Jan???

Last year, just after Dayton, I did in fact email
the Dayton group asking if it would be possible
to get a room for just this reason. I never got
an answer, so kind of forgot about it until just
now as I was starting preparing the slides for
this year's Drake forum. Sure be nice to know
someone on the inside, as email does not seem to
work, even when the email address was what was
specified the correct one to use for this purpose. Oh well.....

If anyone is interested in viewing the Drake
slides, they are posted on Ron's web page. The
last one's posted are from 2010.

My TS 830 is gone and I have some accessories I would like to dispose of.

1. The matching SP 230 speaker in perfect condition. $75 plus @10 shipping.
2. YK88-C 500 hz crystal filter. New, in box. $60 including shipping.
3. Kenwood MC-80 mic. $50 plus $10 shipping.
4, RL-1 relay - New, in K4EAA bag. $15 incl. shipping.
5. 2 Omron MX-2P relays (I know one of them is good, but not sure about the other. I can't remember which one is which, so will sell as a pair for best offer).
Paypal preferred. Contact me offline Marvinkleek@hotmail.com
mailto:Marvinkleek@hotmail.com

73 and thanks. Jim W4ANE

My suggestion to Craig was to use the existing
procedure, but change the 2700hz reference to
3100hz. That would center the passband in the
middle of the filter. Your point is valid, but to
keep the procedure correct as specified in the
manual I thought the 2700 should be changed to 3100hz as a starting point.

If a person wanted more base maybe do something
like: 200hz - 3000hz, or even 100hz - 2900hz,
which is a bandwidth of 2.8khz which matches the INRAD filter.

P.S.

Another interesting idea what be what's been
going on with the discussion of the new 2.8khz
filter that Craig added to his TS-530. Be a good
discussion if we had sweep generator data to
display the pro's and con's..... Etc.... Craig
might be willing to talk on that one.

Ah, "recapping", the number one way to destroy perfectly good equipment.

When people bring stuff that has been "re-capped" to me for the inevitable repairs and reconstruction, I give them two choices - take it away or toss it straight in the e-waste bin.

Why dont you and Craig go in on the new Rigol DSA-815-TG Spectrum Analyzer ($1495.00) and we can do just that and after hamvention I can take it home and take care of it for you and whenever I am not using it you guys can borrow it!

Actually dont need to bring a Sweep gen. Bring lap top with tone generator software, Spectrogram audio spectrum analyzer software, KW hybrid, wattmeter, and dummy load and good to go.

Can also do it with the Spectro gram and no need for tone gen or wattmeter.

I inject noise from Palomar noise bridge into So-239 and couple head phone audio into lap top sound card and you are then looking at your passband with Spectrogram. Can insert tuning tool in trimmer cap and watch as you move the response high or low. Frequency on one axis and dB on the other. Can also watch IF shift and VBT action and off signals if you like. It is loads of fun.

Look in the files section of a copy of a Spectrogram screen print I put there some time ago. It is an off air print so not as clean as what you get with white noise.

Chris

I am not sure what happened here. It could have been carbon track or it could have been 210/300 filter cap failure. I would like to see the board under the caps. From foil view it does not look like a cap failure.

We just had one member who had raspy CW note due to ripple on his Screen grid supply. Replacing these caps fixed the problem. Normally the HV caps are only ones that fail catastrophically and can puke black/brown tar like substance and cause collateral damage to diodes and rect board.

I use to preach if not broke dont fix, but I have modified that where it comes to the HV filter caps. I now replace all that come across my bench. Especially since I started using ESR meter. Often the capacitance is fine within tolerance, but ESR is telling you there is a problem.

I have replaced the 210/300 caps in my personal rigs and found a mixed bag as far as ESR was concerned. I only replace them in customers rigs when they request it. Maybe we are on verge of starting to see more of them fail. I just havent seen any failed or bad ones in the rigs that come across my bench yet.

They are cheap so might not be bad to replace when you replace the two HV caps. It is a judgement call. I always try to make that call based on what will the resultant collateral damage be if they do fail. If this is an example then it is a no brainer.

Mark,

It would be great if the slides from the Kenwood forum could be put up on the webpage aswell, along with the Q&A if possible, only so us small country hams cant get a slight taste. You guys in the state are just spoilt rotten having such great hamfests, if its not Dayton then it's Texas, if it's not Texas then it's Germany. When is it VK's turn?? Oh I forgot we dont have that many people or that many states, lol

Lap tops is included in each room with access to the outside world if needed.

For reference, our Drake forum does not need to use wifi and I simply rely on power point presentation.

I think all those suggestions Terry made are great. The Q&A session has alway been good and can occupy by itself 15+ minutes. Maybe Jan is even a member of the Dayton group and could be the front man to get us a spot? What say Jan???

Last year, just after Dayton, I did in fact email the Dayton group asking if it would be possible to get a room for just this reason. I never got an answer, so kind of forgot about it until just now as I was starting preparing the slides for this year's Drake forum. Sure be nice to know someone on the inside, as email does not seem to work, even when the email address was what was specified the correct one to use for this purpose. Oh well.....

If anyone is interested in viewing the Drake slides, they are posted on Ron's web page. The last one's posted are from 2010.

Topic: 47465 Message: 47524

Ok I have put the rig back together and it seems to be working fine. Good power output and good audio on the other end and good audio here on this end. At the time this happened I was waiting my turn on a net that I check in daily. I had checked in and Charlie W0LAV acknowledged me. We had a few words and all was fine. He said I had a great signal and audio in MO. I had to wait my turn, about 10 minutes listening, all was fine until I went to transmit and the meter pegged and Charlie said he could barley hear me and it was garbled. It pegged once more as I tried to reply. I shut down and fired up the Icom IC-756 to finish the qso. About an hour went by and I pulled it out of line and took off the covers thinking I had popped the cathode resistors. I checked the resistors and they were ok. 5.6 ohms. I got out the service manual to follow the meter circuit and I found that R 10 was cracked and I couldn't read what the bands were. I pulled it out of the circuit and the meter pegged again. So, I assumed that this R-10 played an important part of a voltage divider circuit and went looking to find there were three different resistors being used. I tried a 6.8 Ohm as the middle of the resistors that the circuits showed. Meter did not peg this time but was reading high. I removed the 6.8 and replaced it with the 4.7 Ohm and everything seem to work ok now. Still read a little high but much better. 250 ma at 100watts output 14.175 mhz. I will give it a good shake down tomorrow on the net. Bill WD8OSJ PS: the HV and RF switch selections were not affected by this. I don't think the meter is hurt as it still reads 935/825 volts. And this agrees with the Fluke Meter. ???????

Bill:

Do you recall where you had the meter selector switch when this occurs while checking in to the net? I normally would have it in ALC when running SSB mode.

What position was meter selector switch in when you tried it again? By try again do you mean to load the rig or to use in SSB mode?

How much time would be allotted for a Kenwood Hybrid Users Group forum? I think you said 15 minutes for the Q&A session. Depending on the time limit might want to just focus on one practical topic and use setting the Carrier Oscillators. It does have an element of user preference to it and there are about 4 or 5 ways to do it. Could demonstrate each method and use Spectro-gram to look at the results or use Jeffs Rigol analyzer.

1. Method one requires no test gear. Set by ear. Some do this by listening to off air signal of familiar voice like a net control or some do it by listening to self using the Moni function on the rigs that have that feature. This can be done but is least effective. Would use Spectro-gram to look at the as left results.

2. Method two uses the rigs built in test gear ie the Marker signal and S-meter zero beat method. A very easy method and pretty good results. Could adjust for approx an S7 zero beat and approx S3 zero beat and look at difference in the results again on Spectro-gram. Richard Measures describes the method in the TS830 Survival Guide. One of the few things that is worth anything in that guide.

3. Method 3 would be to use a Frequency Counter and just set to the LSB and USB carrier oscillator crystal frequencies. This is done all the time by folks who just call it good enough. Again look at the results with Spectro-gram.

4. Method 4 would be to use Audio sig gen and Wattmeter (service manual method) and again look at the results with Spectro gram. Some techs believe this is the only way to do it and their position does have some merit.

5. Method 5 would be to just set using Spectro-gram and see results in real time. This is as good as method 4 in my mind.

Maybe something you and Jeff could present as both live close and could set up and practice before the Hamvention? I would be happy to help with the Q&A session even though setting yourself up for having to say "darned if I know" to a live audience!

Topic: 5286 Message: 47528

Hello-
I was wondering if any list members know of where I might obtain these Kenwood items:
1. The coil cord assembly with connectors that connects from MC-50 base to the TS-520S radio. I have a MC-50 microphone and base assembly, but missing the coil cord assembly.
2. The small DC power connector that plugs into rear of TS-520S (for digital display).
Thank you very much,
Byron WA5THJ

Terry,

Great advice.....but pls help us do it right. I have 530SP & 830S in great working order.

How do we proceed with the rotation, given some "old, unused spares" and a perfectly good, working hybrid?

How do we protect our precious Kenwood from damage when rotating the finals?

Do we monitor any particular meter values?

Do we install them, then bring up slowly on a variac?

Do we simply turn on heater power, and leave for a period of time, or operate the Xmtr as well?

Sorry for such mundane questions, appreciate your help.

I forgot to mention I like to rotate spare 6146 finals in and out from time to time. In my experience letting 30 plus year old finals sit on the shelf expecting that they will be viable spares when you have to reach for them has not been a good experience for me.

Dave

Lots of debate on this. You cant really bring them up slow unless you would use a variac or dim bulb tester as the moment you turn on the rig (power on and not the heater switch) you have 900vdc applied to the anodes of the finals. If they are going to arc they need high voltage applied. Some folks replace the cathode resistors and try again after an arc over and find the tubes have not been hurt and work just fine. I never use any again that have arced over. My biggest concern is my panel meter.

Some fellows have an old Heath DX-60 or DX-35 around and they "cook" them in these rigs first. Best way to cook is to remove the SG and Anode voltage and just run on heaters for several hours (some do this for 24 hours) and not easy to safely remove these two voltages unless you modify the old rig. Can lift the anode caps and unsolder the SG lead. But need to be careful and not have these leads contact anything in the rig or worse yet you. I suppose could use an old filament transformer and jumper secondary voltage to the heater pins of the tube.

Some say this is useless as the 6146 uses a flash getter that only works at factory during final assembly steps. So any attempts to cook or getter later is useless as no getter material (typically barium Ba) left in the tube to neutralize any off gassing that may have occurred over these long years. Some think that raising the temperature via the heaters drives off the gas and others say this is bunk. I am in the latter camp. Although I have seen differences in Hi-pot leakage after cooking and cannot explain why. My thought is that cooking wont help but cant hurt.

So what I am saying is there is probably nothing you can do to prevent arc overs. If you had a DC hi-pot could screen tubes and any that could not hold off from 2000vdc to 2500vdc you would not place in your KW hybrid. I home brewed one and screen all my tubes. Average ham doesnt have this test gear.

So what average ham can do is try to protect his rig by trying to limit the fault current that the HV caps, diodes and power transformer sees and to protect the delicate meter movement. The meter is the weakest link in all of this. Can be protected with a simple series string of 3 silicon diodes.

Take a look at my protection mods that Mark Gilger placed on WB4HFN website under the Kenwood Users Group. I have modified all my rigs to try to limit damage from tube arc over. So far seems to be working. Mark has also installed these mods. Some customers request I mod their rigs as well. I can not guarantee the mods will 100% prevent rig damage during an arc over event. So far seems to be working.

Just bought a NOS set of RCA 6146B's on EBay this afternoon for my yet to arrive Kenwood TS-820S, it appears to be too cold & slick in Hodgkins, IL for the UPS folks to be able to work. I'm a new HAM and have a bit of electronics background with the exception of vacuum tubes, so please don't shoot the messenger.

I just had my tube guru buddy (commercial license holder, works big radio stations) tell me the best way to de-gas those tubes is to disconnect the top cap connectors on the tubes (tape 'em, hang 'em up to make sure they don't short against anything) and run the heaters for 24+ hours in order for the getter do it's job as others have stated. Not to mention he said "Don't Key The Mic" while this is going on. Then you can, shut down, button everything up and start the neutralization process. Just passing on the info, so again: YMMV.

Maybe for this first year we could just make it more of a social get together so we can all meet and put a face and voice with a name. Could have a panel and just have a Q& A session. If cant answer the question no harm no foul.

Could also pole the attendees this year about what they would like to see next year and then would have a year to prepare for that demonstration. Could be a live demo or make a video. Whatever vehicle used must be so all can see and hear.

Greetings Terry. i also have an Inrad 2.8 filter in my 530. It is in the original 2.4 slot. Concerning the carrier point adjustment, do I still use the service manual frequencies (300,2.7k) for the alignment? I'm thinking that with a wider filter, these adjustment frequencies would be different to accomodate the wider filter. I have already checked my signal gen to verify that the output level is the same at 300, 1.2k, and 2.7k, so that won't be an issue. Just a little confused as to why use 2.4k alignment for a 2.8k filter.Thanks. Eric KA2PVT

No

When I advised folks to follow the Service Manual steps I was thinking more of the procedural steps and why 50 watts and the constant millivolt injection level were important and not so much the expected and typical roll off points listed for the KW supplied filter.

If you have a sig gen that is continously variable after setting the mic gain at approx 1200 to 1500 hz (can use 1400 hz for your 2.8khz filter) for nominal 50 watts out then just run the output frequency down and watch the RF output begin to fall on the wattmeter and note the frequency when you get to approx 1/2 power and then run the frequency up and watch wattmeter and note upper frequency where see approx 1/2 power. This will tell you where the Carrier Osc trimmer is presently adjusted. I kind of like to see where the as found setting is at before I make adjustments. Dont have to do that can just set sig gen for the lower and upper frequencies you want and adjust appropriate trimmer.

One thing that you may have to do is run the trimmer thru its range multiple times as it tends to sit in one place. These are ceramic trimmers and sometimes will even be slightly stuck and you will feel and hear it move. If cant get stable adjustment can try at the 2nd spot in the trimmer rotation.

Also, make sure you have the IF shift in center position. Sometimes the IF shift pot can be dirty/noisy and if you even touch or tap the knob where you leave the trimmer at will change. You can tell just by the change in the tone of the back ground noise. If you experience the as left Bass or Treble response drifting around much after you set them and turn the rig back over you may have a dirty or even worn IF shift pot.

When all done go to quiet spot on band and turn up AF gain and quickly flip back and forth between LSB and USB and back ground noise should have same tone. Not real scientific but gives you an idea that you have them matched pretty well. I have had times when put covers back on and set rig in normal orientation only to find they have shifted when I did this simple final check. That is why they have access holes in the bottom cabinet so owner can have easy access to adjust them.

So Mark Gilger was right that I was not correct advising to literally follow the service manual steps. Need to adjust for the upper and lower frequencies depending on the characteristics of the after market filter you are installing.

Sorry about that.

The switch was in IP position. I normally switch it to ALC mode, but was a little rushed and forgot. The rig stays on 14.304 most of the time and I never retune it unless I switch bands and that is not very often as I use the 530 to work other bands most of the time.
The meter would peg just keying the mic in SSB mode. That is why I thought it was the cathode resistors..
But they were fine. 5.6 ohms. The only resistors I found bad was R-10. Replacing it cured the problem. Why it went bad, who knows, age I would assume as it was an old carbon style 1/4 watt. The rig seems to be working ok now as I talked to Texas last night on 20 M and got a great report barefoot.
I turned the rig on and let it warm up while I was typing this and I just keyed the mic and I have idle current of 60 ma. On the dummy load, which I wish everyone would use, I get 110 watts output with 240 ma current.
That is using my Bird 43 watt meter. I have to leave for a appointment and will let you know what happens later today.

Topic: 47465 Message: 47538

Ok and did you also say then after that first event that you removed R10 and with it removed or lifted from the final board you keyed rig again in SSB mode with the meter in IP that it pegged again.

If so, you are telling me the meter pegged in IP position with the failed resistor in and out of the circuit. Is that correct?

One thing you have to remember is that in SSB mode with no mic input and you key the mic should only see 60ma zero signal plate current because all that has changed is that you have switched from cutoff bias to operating bias on the 6146 control grids. There is no rf drive. Of course always best to check this with Mic gain at minimum so no modulation to cause higher Ip.

So keying rig in SSB mode and pegging the meter in IP position means the meter had to see very high IR drop across the cathode meter shunt resistors or the meter multiplier resistor R6 had to be shorted and then only takes 0.40vdc to peg the meter. You report R6 us normal resistance so meter should be configured to measure a max of approx 1.75vdc.

Only fault I can think of that would cause the meter to peg in SSB mode with R10 in and out is loss or change of operating bias voltage. I am still suspicious about this.

Only way I know for R10 to affect the IP reading is for it to go very low which would then cause your 5 ohms to go very low. This would result in low IP and not pegged IP.

Mike W5RKL --Please add any insights you may have. I have pretty much exhausted any ideas.

Bill --Please confirm meter behaved same way with R10 in and out of the circuit. Meter pegged FSD in SSB mode when mic keyed.

With the bad resistor the meter pegged and without the resistor it also pegged the meter. There was not a mic plugged in at that time and I was using the send / receive switch to transmit.
I replaced the bad R-10 and everything is normal. just checked into the net and Charlie said I sounded
like my old self sitting in the chair next to him. I was using about 25 watts on the peaks. I really like
this 830. It is much better than the 530, but the 530 ain't no slouch either. I run the 530 on 40 / 80 meters.

Ok Bill appreciate the feedback as I am trying to understand this anomaly. As I previously related you can remove R10 from any TS830 or TS530 and throw it away and the meter circuit will function just fine.

If you want to see its effect just lift one end and bring out jumper leads and load rig to say 200ma and then touch R10 on and off the circuit and you will see perhaps a needles width of movement. The higher R10 ohmic value the more accurate the meter reads. The lower R10 the lower that Ip will read.

As to how you found it at 55k ohm and burned and cracked with no ill effect on R6 2.7k meter multiplier is a mystery to me. If you should experience this again I would clean the bias voltage adjust pot and run it thru its range a few times just to be on safe side.

One thing I forgot to ask is if you have the original cathode resistors installed or not. Pretty easy to tell. My guess is they have been previously replaced and R10 is remnant from that event?

Important thing is rig is working now as it should.

Enjoy your TS830

Here is a slew of longer cables on eBay, not cheap though, they run about $25. There is also my mic with silver contact micro switch upgrade in the base farther down the page:
http://www.ebay.com/sch/i.html?_trksid=p3984.m570.l1313.TR0.TRC0.Xmc-50+microphone+base+cord&_nkw=mc-50+microphone+base+cord&_sacat=0&_from=R40

The mic cables are 6', you could cut one down and have a spare for 20 years from now when that gets tired.

The power cable you need, I'm not sure on, just woke up and Caffeine IV is just beginning to trickle.

Someone here I'm sure has both in the parts box if you can get them to dig the cables out for you.

Can I continue to use my siglines if I restrict myself to non-confrontational/non-upsetting ones?(I've seen others using them this week). Hard habit/tradition to break.

Yes Terry-
I found quite a bit of data on TBL and I ended up removing the long wiring loop over to the IF board and simply soldering a 3.9K resistor between TBL and RLT on the RF board.
Actually, before I found the info in the archives, I had measured the resistance on the components on the terminal strip at 3.8K, traced the wires out to TBL and RLT on RF board, chose a 3.9K 1/4 watt resistor and had soldered the resistor in place on RF board. I did this because I thought it was a mod, and if it really was factory it was a little out of character with the rest of the construction.
I tell you, I do not like the receiver in this TS-520. I have been able to greatly reduce the 3.736 spur in the receiver, and I have gone through the alignment several times. It aligns beautifully and the receiver is really hot, however when I turn on the calibrator it is hard to find the actual calibrator signal for all of the spurious signals about every few KHz. The calibrator signal is not that strong on the higher bands (about 5-7 on 28 Mhz) but the spurs are being created, I have not investigated it any more, This is the only TS-520 that I have ever owned or gone into, I have a number of TS-520S models here and none have ever exhibited this behavior.
Thank you for all of your help here.

Date: 2014-02-07 18:36:52 UTC
From: Joseph Stiles
Topic: 47547 Message: 47547

Greetings Group,

I hope everyone is doing well so far this year. I have received several questions & complaints
regarding "sig(signature) lines" that are attached to posts/msgs. So, I know it is not going to make
everyone happy...but, we all can learn to live with certain restrictions.

"SIG (signature) LINES" will be permitted under the following guidelines:

Generic "sig-lines" only! For example, what Bob Macklin signs: "Real radios glow in the dark," is just
one of any number of examples that would be permitted, BUT let's not over react.

Overt political, religious, or derogatory statements will not be permitted....AR

I, and the moderators, try our best to administer this group and know not everyone is going to be happy, no matterwhat we do. I do not care what is allowed on/in "other groups." This is not the "other group(s)."

The groups "policy/rules" section will be updated in the near future, to reflect this change.

So, let's work and play well with others...OK?

Thanks for your attention to this matter

There's much info posted on the web. I have made a few setups to perform reactivation of glass, and as well as ceramic tubes following these guidelines on PA0FRI's webpage:
http://pa0fri.home.xs4all.nl/Lineairs/Tubes%20reconditioning/tube%20reconditioning.htm
Configure the tube into a diode and check its conduction as a test. Yes, its not a complete characterization of the tube, especially a tetrode, but its easy to do. I have tested quite a few 572b's triodes to sort out the good and the worn out ones.

When I first got this rig about 8 months ago. The gent I got it from said he use it to run RTTY and a lot of CW.
He warned me ahead of time that It may need some work an alignment. On 24.5 and 28 it was almost impossible to load more than 20 watts. So I dug into it to see what was going on. I pulled the tubes and went over to a friends house that restores old antique radios. He ran the tubes through his Hickok tube tester. the driver tube was a little on the week side so he found a good one in his stash and gave it to me. The 6146 b (GE Brand) check 100% good. no shorts and no gas. I came home and replaced and as I pushed one of the finals in I saw a crack in one of the cathode pins solder joint, I pulled the tubes again. Remover the final board completely. Cleaned it and checked all the resistors. The cathode resistors were 9.7 ohms total. I had a spare set from Ken and I replaced them and the screen resistors. and the R-11 resistor on the rectifier board. I also had a kit for the final cage and changed that also. I re-soldered all the pins on the tube sockets and removed the af board and the panel and re-soldered all the pins for the driver tube. Cleaned and lubed the fan. Cleaned the band switch and checked the coupling. It is ok. Took it outside and pumped up the compressor and blew out all the dust. I reassembled everything very carefully and plugged it in. As you can see I tried to do it right. I turned it on and went for dinner. I came back 1/2 hour later and it was good and warm then. I checked all the crystal frequencies and found them to be in spec. Also cleaned the VFO and re-lubed it. I got it to load 115 watts on 14.175 at 230 ma. I thought this was pretty good. 10 m and 15 m came up to 90 watts. I went to 160 and loaded 125 watts at 230 ma. Wow this thing is good. The new driver tube and a hand full of upgraded parts did the trick and is has been that way ever since. Until Monday. I keyed the MC-60 and checked in and said a few words to Charlie and waited my turn. When that came I keyed the mic and the meter pegged and Charlie ask what happened. It did the same thing a second time.
I shut it down and turned on the IC-756 and explained to Charlie what had happened. After that I unhooked it and pulled the covers and that is all I found that was bad. I took the finals again to my friend and he said they were great. No sign of arc over as the capacitance on the elements checked fine and up to speck. He said when a transmitter tube arc's it changes the components inside the tube because it burns a wire or two from the grid circuits. He showed me a sweep tube that had arced over and you could clearly see the damage. SO why this did what it did, I have no idea as you said it shouldn't do what it did. Is there anything that RL-1 could do to cause this? I have a new one on order from Ken, but he may not get them for awhile. I also ordered one of those replacement relays with the twin relays on it to try out and see if it is as good as they say. They claim that it is better as it is sealed and in a vacuum. Do you know of any mods that will slow down the speed of the VFO as you turn it.25 kc is awful fast to me. The 530 is the same. Have to look for a planetary drive like 10 to 1. I hope all this answered any questions you might have had.

Terry, the mirroring on the inside of the envelope is from the getter, and it is still oxidizable. That could be the source of the decrease in leakage at HV. I have a gassy 12BY7 in Apache, and the dull purple glow has diminished since using this old rig.

Yes I think you are correct it is due to the remaining barium on the flash on the glass envelope. But why doesnt it react with the gasses that have leached out while sitting at room temperature? Why does it take elevated temperature to accelerate this?

Only reason that they use high RF induction is to cause very high current in the getter ring near end of draw down to cause the nickel shield liner "weak link" on the getter ring to rupture and expel or flash the barium on the glass envelope. After that the barium and doping elements inside the getter ring do nothing.

I suspect it is as you say the result of the action with the barium in the flashed coating that remains there to contain any occluded gas that leaks out over long time. Just dont understand the need for filament heating.

I once saw a video where the fellow took a perfectly good tube with flashed getter and cut the glass tit off the top of the tube envelop and you could watch the flash coating slowly turn to white powder as the atmosphere that entered the tube was oxidized by that residual barium. A very telling experiment. No heating required for that action.

Terry K9TW

47557. RE: Meter pegged in IP on transmit on TS-830

Bill:

Yes very good detailed history. No I dont know of any way to slow down the VFO tuning rate other than rube goldberg mechanical mods.

When a 6146 arcs over it typically arcs to the beam forming plates as they are physically the closest to the anode. The beam forming plates like a suppressor grid is electrically connected to the cathode which is connected to ground thru the cathode meter shunt resistors.

A 6146 tube can arc over and you will not be able to measure or detect any damage of any kind. Will be no difference in Cgp or Cgk inter-electrode capacitance. Your friends experience is quite different than mine. No way to use a ohm meter or LCR bridge to determine if 6146 tube has suffered any damage.

In 10 years I have had 2 rigs across the bench that arced somehow from the Anode to the Control grid as opposed to the beam forming plates. Now that is not pretty as it causes a lot of damage to everything in the FG and bias circuit including damage to the final board, the ALC amp circuit, AF board molex connectors, the bias pot ruined, and all the way back to -C supply. I have not seen an Anode to SG arc over that was evident.

It is possible to have a 6146 arc over and incur no detectable tube damage and many folks replace the cathode resistors and try the tubes again and will experience no problems after that. I do not do that. I dont trust them. I DC hi-pot and if tube wont hold off 2000vdc to 2500vdc I wont put in my rig. Remember with RF drive you are seeing approx 1600 volt anode swing.

I think I mentioned that I have hi-potted spare 6146 tubes and seen excessive leakage at 1000vdc and then "cooked" them in an old DX-60 overnite and hi-potted again and seen improvement up to around 1500vdc. Not sure why this occurs unless the elevated temperatures causes what remaining barium that is flashed on the glass envelope to be more reactive? I have no clue why leakage improves somewhat after "cooking". you would think that cooking might even drive out more occluded gas? However, I have never been able to take any 6146 that wont hold off at least 2000vdc and improve it by cooking for any amount of time. Can "cook or getter" until the cows come home and wont lower the leakage current.

So it is up to each individual if they want to try the finals again after an arc over that has resulted in cathode meter shunts popping open. Now if they have popped open due to thermal runaway that is a different matter. Almost always the finals are destroyed. There has been element melting and sagging and internal shorts introduced.

In my opinion you cannot prevent arc over, but can prevent and limit damage by installing protection circuits such as the ones I have proposed and installed in my personal rigs.

47558. Vaccum tubes, Getter Flash, and other vacuum tube discussions

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-08 03:46:30 UTC
From: W5RKL
Topic: 47465 Message: 47558

Everyone,

Below are some interesting reads about Barium, Zirconium, gas absorbing material used in vacuum tubes.

The Getter Flash discoloration myth:

http://tubesound.com/2008/09/30/brown-or-black-getter-flashing-does-not-mean-used/

Barium getter flash:

http://education.jlab.org/itselemental/ele056.html

http://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=2&ved=0CDIQFjAB&url=http%3A%2F%2Fwww.saesgetters.com%2Fsites%2Fdefault%2Ffiles%2FBarium%2520Getters%2520Features_0.pdf&ei=IqH1UpbpOIi2yAGsrICYBQ&usg=AFQjCNFd2tlRFhtWuzb8SyAbh_tHlGUCnw&bvm=bv.60983673,d.aWc

Another link that discusses gas absorbing in vacuum tubes, including high power tubes such as the 811, 572B, and while not indicated, it also includes the 4-400 and 3-500Z. This link also covers additional vacuum tube information such areas as bias, blue glow, amplifier classes etc. A very good read for the newbies and others as a refresher:

http://www.vacuumtubes.net/How_Vacuum_Tubes_Work.htm

47561. Meter Problem with Kenwood TS-820S

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-08 06:29:38 UTC
From: <big_argus@...>
Topic: 47561 Message: 47561

Today I received a decent Kenwood TS-820S I purchased on EBay. The iInside was a bit dusty, looking as if no one's been inside of it since new. All frequencies read proper, so it hasn't been hi-jacked for a CB rig and it had the original Trio SSB & CW filters already installed. All slugs appear to have never been touched. Overall the radio appears to be in excellent shape as seller described with one exception, the meter for RF, ALC, HV, etc.... No mater what position I place the meter selector in, it reads what appears to be the ALC function. If I turn the RF gain all the way down the meter reads full scale, as I turn it up the meter heads towards the bottom of the scale and pumps in relation to any signal the radio is receiving.

Neither the user manual or the service manual has much info about the meter other than the general operation and just a couple of mentions in the troubleshooting guide concerning non-operation for 2 or 3 functions. The block diagrams and schematics aren't much help either (just got some new glasses yesterday and that might be part of my problem reading the schematics). I checked inside for a possible lose connector or relay that had come out of it's socket and found nothing amiss.

I'm a new ham with this being my first HF radio and first radio period with more than simple adjustments for basic functions, so I'm at a bit of a loss with this problem. I do have some long term experience in professional audio electronics and computers, so I'm not totally illiterate with a lot of what's going on here (I've built several recording studios over the last 30 yrs and maintained, rebuilt large format mixing consoles & tape machines). I'm not quite ready for "No Time For Sargents" type percussive maintenance either, you know, spit in the back of it and womp it real good. Any help in pointing to a solution or in the general area of one would be greatly appreciated.

Mike:

If I can find the video I will post it that shows normal brown black coloration on top of a used miniature tube and the getter ring oriented horizontal at top of tube that produced the flash deposit on the glass. It still has the typical dark color material even after having years of service.

Point the guy was showing that after the initial gettering the deposited barium was still active and would address any subsequent off gassing for many years as long as didnt have any gross atmosphere in leakage at the seals.

The guy takes a pair of dykes and cuts off the sealing tit and leaves camera on the tube and very slowly that dark brown/black coating turns milk white. I cant remember how long it took but as I recall it was pretty quick as that is a lot of atmosphere in-leakage many many times more than would result in internal metals and ceramics off gassing during life of the tube.

I have also watched these guys build vacuum tubes in their garages and most of them break open old TV vacuum tubes (horizontal damper tubes) and break the getter ring off and look at it with magnification to see if the nickel sheath is pretty much in tact other than at the break from the initial RF induction heating to see if has sufficient barium to be installed in their home made tube and be heated near end of draw down and flash their home made tube. Very fascinating stuff to watch.

Too me one of the things that is under appreciated is the tooling that it takes in the automated process. Mullard has really good video series on the process.

James,

In receive, the meter is just an S-meter.
In transmit, it shows the other parameters.

In RECEIVE, set your POWER switch to ON, HEATER switch to OFF, METER to HV. Flip the SEND switch up for a few seconds and observe the HV reading. (red scale should read between 8 to 10). Switch SEND down to REC. Report back.

James:

You will love this rig. It is a design and engineering marvel.

Think about it a minute and no need to consult the schematic just yet, but can do that after thinking about it.

In Receive mode the meter is measuring the AGC bus voltage no matter what position you place the meter switch in. It does that as the meter is being connected to the AGC bus thru a normally closed (NC) contact on the Aux relay. Some folks call this the TR relay and the other relay the ANT relay.

1. In receive if you flip to Ip there would be nothing to display as the final tubes are turned off by the cut off bias applied to the control grids. There would be no reason or useful information to be gained by ever looking at IP in Rx mode

2. In receiver if you flip to HV you could monitor the B+ or anode voltage as it is on the tubes at all times, but it is meaningless as not required for Rx mode. Again this is controlled by relay contact.

3. In receive if you flip to RF there would be nothing to read. RF position samples the RF output voltage at your S0-239 connector and nothing there with no RF drive in Rx mode. This position will be used to load your rig in lieu of an external wattmeter.

4. Lastly you would never place meter in Compression position in Rx mode as you are not speaking in to the microphone and modulating the radio. This meter position will be used in Tx mode when you turn on the RF compressor and modulate the rig. Typically not used unless chasing DX.

So what you describe is normal. No matter what position you place the meter switch in Rx mode the meter is measuring the voltage on the AGC bus as the Aux relay closing coil is not energized and relay contacts are as you would find them with relay sitting on the shelf. That AGC bus voltage is approx 3.2 vdc (where ever you have set RF-1) and the meter displaying zero unless you turn the RF gain pot down or if you receive an off air or Marker signal (25khz xtal calibrator). When that happens the meter will read up scale as it is a FET based reverse reading voltmeter and is displaying the voltage level that is now lower than 3.2vdc.

Now armed with this dig in to the schematic and study this to validate what I have told you..

The last paragraph makes a great point. I've been conditioning tubes for several decades, mostly boadcast tubes, but with the supply of good new old stock tubes dwindling (even NOS tubes generally need a burn-in period now since many have been sitting decades) it is good practice to do the conditioning in a device and a place where if the smoke flys the fire danger will not burn down the house and the hazardous gasses will not sicken or kill its occupants if the rig will be left unattended over night.

I've never had a rig smoke from conditioning tubes, but the photo proves it can happen.

For #2 what I was trying to say is it would be technically possible to have the HV position read in Rx mode, but little would be gained by it as the final tube anode voltage is not used for anything in receive mode. You need to know if it is available in TX mode and what level it is with no RF drive and with RF drive. So if you think about it you should not expect any indication in the HV meter position in Rx mode.

Here is a simple 6146 tester you can build that has been around for some time. It essentially configures tube as a diode as well (control grid and cathode tied and anode and SG tied).

I only caution there is more to testing them than checking emission.

The 820's meter switch positions are disabled in receive by relay terminals RL-3.

The meter displays variations in the receiver's AGC circuit (S Units) in receive. None of the meter switch settings are active in receive.

Heathkit displays the final tube's HV in their SB-100 series transceivers and SB-400 series transmitters in both standby (receive) and transmit. The HV is not used in any other circuit than to provide plate voltage to the 6146 final tubes. So what useful purpose is there by displaying the final tube's HV in receive since both final tubes are biased to cut off???

Mike are you posing the question to me?

What I was trying to do without telling him to read the manual which by the way is very good advice for any new KW hybrid owner is to "think" about what they are looking at and what would be a logical expectation for what they perceive as a problem. Before doing that I would read the manual. Then if still confused and thinking about it doesnt help then ask the group.

Sometimes the manual could have a little more meat on the bones and that is the case with the TS820 when it talks about meter positions. It never really explains that the ALC position in Rx mode is the S-meter position nor does it say that all other meter positions are the S-meter in Rx mode. It talks a lot about the ALC function. Maybe they should have labeled that meter position AGC/ALC?

I was trying to tell him that when thinking about it of course is technically possible to display HV in Rx mode and I did not want to confuse him by my original comments that he should expect to see HV displayed in Rx mode on his 820 as it really would not be very useful as it serves no purpose in Rx mode.

Probably at this early stage should have just said that the meter switch displays S-units in all positions in Rx mode and what he was seeing as a problem was normal operation and not tried to explain why. Hopefully why will come sooner than later.

My worthless 2 cents on your question: To see if the HV section is working (at all) when a dummy load or antenna is not available. Like maybe at a swap or venue not conducive to full testing of the transmitter.

There are at minimum two things you need to know about the HV

1. That it is 900vdc and not 450vdc or less

2. That it is capable of typical regulation level of a voltage doubler anode supply under approx 200ma load.

Yes you can validate #1 in Rx mode, but you need Tx mode for #2.

Also because you have 900vdc displayed at the meter does not mean you have it on the anodes of the tubes.

Kind of sorry I brought it up. Trying to teach a way of thinking and studying these radios and wrote a confusing step. Yes it is perfectly logical to expect to see HV indication in Rx mode and some rigs do just that, but not KW hybrids and not really as useful in RX mode as it is in TX mode.

Never meant to start a discussion on the merits of being able to read HV in Rx mode. We all have better things to do than that.

Sorry about that.

No Terry, the post was to the members who may not know the meter switch is disabled in receive. I should have made that clear when I posted my comment, sorry about that.

For those who don't know the meter displays only variations in the receiver's AGC circuit in receive as outlined below. You can follow the comments below by studying each of the KW hybrid schematics.

TS-520/TS-520S/TS-520SE relay RL2-2 terminals disables the meter switch in receive. The meter is connected to Q8 on the IF Unit board through relay terminals RL2-2. Transmit ALC circuit is disconnected by relay terminals RL1-1, to the left of the IF Unit board on the schematic. Relay RL1-1 feeds variations in the output of the receiver's AGC circuit to the IF Unit's "AGL" terminal on the IF Unit through relay RL1-1 which controls the gain of the IF stage.

TS-820 relay RL2-3 terminals disables the meter switch in receive. The meter is connected to the collector of Q5 on the IF Unit, displaying variations in the receiver's AGC circuit. The ALC circuit is disconnected to the meter's ALC switch terminals by the Relay Unit plug RL-3 pins 1 and 2 and relay terminals RL-14.

TS-530 relay RL-1 IF Unit relay terminals between IF Unit plug 10 pins 2, and 3 disable the meter switch in receive. The IF Unit relay RL-1 terminals, plug 10 between pins 2 and 3 connect the meter to the collector of IF Unit Q8. The ALC is disable by the relay terminals to the right of IF Unit Q19, located in the middle of the IF Unit board schematic, on the IF Unit board. The meter display only variations in AGC voltage based on the strength of the receive signal applied to the IF amplifier is displayed on the meter.

TS-830 relay RL-1 on the AF Unit board controls the meter connection to the meter switch, plug 7 pin 6 through relay RL-1 terminals to AF Unit board plug 10 pin 6 (SM). The meter is connected to IF Unit plug 9 pin 2 (SM) which connects to the collector of IF Unit Q12. Transmit ALC is disabled by the AF Unit relay RL1 terminal on plug 7 pin 2 (TM - Transmit Meter).

Sorry for the confusion.

47574. TS-830S Gold and Factory-installed filters

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-08 13:38:58 UTC
From: <mpocciotti@...>
Topic: 47574 Message: 47574

Hello everyone,

I know this has been discussed here before, but I think I have new information on the subject.
As you have read on a previous topic, I was lucky to find a NEW TS-830S that has been in storage for 30 years (or more). For all practical matters it is a new unit. It is also a Gold Label, but it didn't come with the optional filters installed.
Please, check the article on my blog and the pictures
http://ts830s.blogspot.com.br/2014/02/ts-830s-gold-label-and-factory.html
http://ts830s.blogspot.com.br/2014/02/ts-830s-gold-label-and-factory.html

Please, let me know what you think.

73!

to Mike W5RKL

Thanks for the response, with measurements.

The 150W run was a short test series of "V" in CW mode.
I noticed immediate flat-topping of power as a quick increase of Carrier was done, then key-up.

I really appreciate the following data You wrote:
quote/
Heathkit designed their ICAS Class AB1 6146 based final amplifiers with plate voltages of approximately +820VDC from their HP/PS 23 power supplies. My SB-100 which has a pair of 6146As, when tuned up into a 50 ohm dummy load for maximum input power, the grid current is at 2.5ma per tube (5ma total),)grid current remains stable), and plate current is at approximately 225ma with 730VDC plate voltage which equates to approximately 165 watts DC input and approximately 98.5 watts "output" (60% efficiency) to the antenna/tuner.

No need to push for more power, 98 watts is more than enough to work anyone I can hear. I work into Japan with a simple 40 meter inverted vee up 25 feet and 98 watts output. I have an AL-811 (3 tube version) but I don't use it that often, don't need it.
/quote

All the guys would do well to use a conservative Power Level.
The 6146 Tubes would last much longer at 66W EPO.

The Kenwood 830 is a "Cadillac" amongst older transceivers.

Thanks a bunch everybody! I was thinking in the back of my head that some meter functions might not be available until the radio was put into transmit mode, but wasn't sure. We used a long wire to check the receive function of the radio since the only proper transmit antenna I have is a 2m/70cm Slim- Jim. My weekend ended yesterday, so it will be next week before we can put up another antenna. At the advice of some long-time Hams I know we're going with a multi-band dipole starting with 80m & 40m, adding other bands later. This also makes me feel I got a good deal on the radio. I've been reading a couple of horror stories here about butchered radios on EBay that CBer's had tried to convert, so I was a bit apprehensive for a moment.

Once I won the bid on the radio, I've been purchasing spares/replacement parts. I've already picked up new mic connectors, lamps, VFO plug, and NOS sets of the 12BY7A and 6146B tubes. I'm also building a paint can dummy load, just waiting for a few of the remaining parts to arrive.

Thanks again for all the great replies!

Thanks for all the great advice! What got my attention upon first turning on the radio was that the meter immediately went full scale in the HV position, in my experience with audio related stuff this is not a good thing.

I'm at work and don't have much time at the moment, I have a post on my computer at the house waiting for me to hit reply since I got a phone call just before leaving. I'll do that when I get home. LOL!

In the mean time just use your long wire to roam the bands and familiarize yourself with receiving on HF.

40M early evening. 80M late night.
20M and 15M daytime.

No problem. I just knew that my original number 2 statement could be read as he should expect to see HV reading in RX mode and I was trying to say that yes logically you could assume that to be the case and is true for some other mfg rigs. Need to do better job of proof reading my responses.

How the AGC bus works and the S-meter works confuses a lot of folks. I read a lot of flat wrong info about it being put out on the other reflectors. Same with ALC. The other day a fellow was asking about why he had no ALC indication on his KW hybrid while loading the rig and an old timer corrected him and told him he should be looking at grid current and not ALC! If you told him max grid current in Class AB1 is approx 45ua he would scratch his head. This is still the best store in town as far as I am concerned.

I had a fellow tell me one time....."Terry your problem is you Think too much" Upon reflection I Think he may be correct!

Of course have to be careful not to get into "analysis paralysis" as they say, but I sure do enjoy dissecting these circuits and trying to figure out how they work. Lots of hours measuring and even bread boarding.

I am not sure whether I would enjoy more finding a garage full of NOS parts in Japan or a garage full of the design basis documents? Heck I would take them even if written in Japanese.

James

Make sure you hit that Owners Instruction manual and down load the Service Manual as well. Good to study the Block Diagrams and read the circuit descriptions. Manuals should be dog eared. Dont try loading until you have that dummy load built and tested and connected to rig.

You do need to know that the documentation for this rig for some reason has the most errors. These at times go way beyond typos, grammar, and translation.

OK to gather up all the Mods as well. However, I would not install a single one of them until you come back here and ask about it. Most are voodoo and based on anecdotal reporting from owners who had problems with cause and effect.

Lastly realize there are lethal voltages inside this radio. Been covered here time and time again.

If that is true then you had the rig flipped to Send and the meter in HV position. Should not have gone to FSD but could have gone to over 900vdc. As a new owner I would leave the Heaters off at this time and always make sure rig is not flipped to send or mic locked in PTT position.

I always look at the pictures on Ebay and most of them scare the hell out of me. I see heaters on, send switch to send, CAR level pot turned up, sometimes meter indication in RF or IP positions. I cringe when I see this stuff as it means seller has no clue and rig can be damaged easily. Hopefully no more than the finals, but could damage the RF plate choke. I would never buy one of these unless could get it at parts rig price.

If you saw this when plugging rig in for first time, then I would suggest a very good visual inspection of the PA cage. Take a look and make sure you have correct fuse in the rig as well.

I hope what you saw was the S-meter peg and it will do that on initial power on unless you place rig on dummy load or ground the center pin of your SO-239 rig. I dont like to have mine bang against the peg although it does not seem to hurt the meter after many cycles of that action. Too much to explain why it does it here. Just good practice to use a antenna switch with grounding positions and leave rig there when not in use. Not only to protect the meter but to protect front end from ESD.

Everyone,

Some members may have difficulty following the schematic wiring, especially in the TS-830. The TS-830 schematic wiring shows wires coming from a plug pin or terminal that appears to become part of a single wire. For example, look at the 830's Rectifier Unit's "SG2" terminal. A wire comes off the Rectifier Unit's SG2 terminal then is becomes part of what appears to be a "single" wire. That "single wire" which is not a single wire but rather multiple wires, goes up from the Rectifier unit then branches to the "left" to the "SG2" terminal on the Mode switch. The Mode switch "SG2" terminal is the other end of the wire that's connected to the Rectifier Unit's "SG2" terminal.

The key to following the TS-830 schematic wiring is to note the beginning label then follow the wire as it enters the "single wire" until you find the end that should have the same label.

There are some labels that don't have a start and stop label, for example the meter label "M". The meter has only two connections, one to ground (chassis) and the other to the 830's AF Unit board, plug 7 pin 6 labeled "M". Pin 6 connects to one segment of the AF Unit's "SPDT" RL1 relay. The position of the movable relay terminal determines how the meter is connected and the relay moveable terminal only moves/changes position when the relay, RL1 on the AF unit is energized or de-energized.

The meter switch "wiper" is labeled "TM" for "Transmit Meter" which connects to the AF Unit plug 7 pin 2 labeled "TM". TM then connects to a fixed relay terminal on the AF Unit board. The fixed relay terminal is shown in standby/receive. The meter connects to "TM" ONLY when the AF unit relay is "energized" which causes the moveable terminal to switch positions and that only happens when the 830 is switched to transmit. This is how the meter switch is "disabled" in receive and only displays receive S Unit from the IF Unit.

If you follow the other hybrid meter wiring you will see similar wiring and control circuits that switch the meter from S Unit only in receive, to ALC, HV, IP, and RF in transmit.

Very good point Mike. A schematic or an elementary diagram is never intended to be an as-built drawing. It shows how it works electrically.

You need a wiring diagram to see the actual routing of the wires. Very seldom does a radio manufacturer provide a complete wiring diagram. May get a chart that shows the termination points and colors and designators if you are lucky. Also you can not rely on color code conventions. In electrical control panel design always get a wiring diagram in addition to an elementary (electrical version of our schematics).

So points that may be shown inches away or on other side of the schematic can actually be landed at the same physical location in the radio.

I've got both the service and owners manuals on my PC at home.The description of the panel meter above by Mike is extremely useful and appreciated.

40 yrs ago my Dad repaired a broken rectifier tube my cleaning off the glass base and building a solid state rectifier upon it. Worked great, at least until I stuck my finger in it by reaching around the open chassis for leverage to remove a mic cable from the front. My left arm swung like a pendulum for about 20 mins. I've been painfully aware of HV ever since.. LOL!

The radio was not on send Terry, the RF gain was up about halfway and there was no signal present (I think the tuner was set to 28 MHz). Once I found a signal on 40m I could bring the RF gain up and make the meter pump downwards with the audio as the ALC should behave..I've done a pretty thorough visual inspection taking some hi-def photos I could blow up in order to see finer detail and nothing seems amiss. As I stated earlier, the internals are dusty, but appear that nobody's ever been inside it.. At this point I think other than the meter lamps not working (I have new replacements) I'm GTG. I have all the parts except for the resistors to build a paint can dummy load with the resistors due in any day. Thanks for the reply.

We do not know what position the AGC was in and I still hope what he saw was S-meter and not HV. I dont want to turn on any hybrid and find I have a keyed relay.

What you say is true in Slow should see a very rapid but not very far deflection maybe S4. Hard to see as it is rapid. However why have to remember to switch the AGC to a "safe" position anytime you shut the rig down? Also, why exercise that switch more than you need to?

I still submit best practice is to ground the SO-239 or place on dummy load. In the case of the TS820 as you point out it protects the meter if AGC is left in Fast position and it protects the rig from ESD.

Terry K9TW

47595. Re: [TS-520_820_530_830] RE: Meter Problem with Kenwood TS-820S : pegging meter at power on

Terry,

My frame of reference is the way I operate my TS-820S "SSB TRANCEIVER".
For me, SSB SLOW is the norm. No need to move the AGC switch.
Of course, other modes may require FAST.

Your last para : Do you mean
if left in FAST, grounding or dummy load protects the meter from pegging and ESD?

My rig pegs on dummy load or grounded when in FAST.
Protected from ESD but not from pegging.

Rig hits S4-ish in SLOW, grounded, dummy or dipole.
On my rig, grounding or dummy load has no effect on pegging.

Grounding against ESD and SLOW against pegging is safest?

Dave

James,

You said once you found a signal on 40 meters, you could bring the RF gain up and make the meter pump downwards with the audio as the ALC should behave. The meter, in receive, is not displaying "ALC" but rather displaying variations in receive AGC voltage produced based on the variations in the receive signal level. "ALC" is a transmit only gain control voltage and is only produced during sideband transmit, never in receive.

47597. TS-520s Aux 12v power loss...

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-09 02:07:30 UTC
From: Timothy Johnston

Okay.. made a little mistake tonight.. accidentally shorted the 12v aux out on the back of the rig that is normally used for the DG-5. No more 12v and immediately lost all receive noise. Shut down the rig. Any suggestions before I open her up tomorrow? Anyone have a clue on what might have blown? - fuse, resistor, something else? easy fix? or nightmare?

Not sure what happened but appears my response didn't make it.

Anyway, it appears you have blown the 2 amp DC fuse located in the fuse holder directly below the fan on the rear panel. Replace the fuse and you should be back in business.

I suspect you blew the 2 amp fuse in the 12VDC supply output. The fuse is located in the fuse holder directly below the fan on the rear panel.

In internet terms, lolololololol, don't I wish.

I had probably the same thing happen when I plugged in the digital disply to my 520SE.

But, WAIT! The fifty cent fuse was SAVED!

By the noble and heroic sacrifice of the lives of the D8, D9, D10, and D11, as well as their copper traces, on the Rectifier Board (X43-1090-02, IIRC).

If the fuse replacement doesn't fix your problem, examine the rectifier board and look for burnt (as in MISSING) traces, and diodes that are cracked in half, in those positions on the rectifier board.

Good news, they're just any sort of 50v or better silicon rectifier diodes. Cheap replacements. Bad news is that these boards have some of the thinnest, crappiest copper on them you'll ever see. If the diodes went, and if it's anything like what hit mine - TWICE, the traces won't even be there to bother worrying about lifting them from the board substrate when removing and replacing the diodes. Makes removal easy, which could be construed as good news.

More good news, though, is that you can just stick the excess diode leads through the holes and make them do the duty of the missing or lifted (HOPE yours are still intact, be prepared for them to be carbon) copper foil traces on the bottom of the board.

(If they're "only" lifted and not completely toasted, clear nail varnish or coil finishing varnish will stick them down again.)

Now here's a hint, I wish I had followed last summer:

GET PHOTOS OF ALL OF THE CONNECTIONS ON THERE BEFORE YOU PULL A SINGLE WIRE OFF THIS BOARD.

Use a digital camera, take all kinds of photos of the thing as it sits and is hooked up now. Electrons are cheap, snap a LOT of pictures.

THEN unwrap and unsolder and remove all the wires, then pull the board and repair it. Those photos will take the anxiety out of hooking up the high voltage lines and power transformer connections later. Yes, you will mark the wires with flags or something, but those have been know to fall off. I know they did when I was doing this back in the summer. Learn from my mistake, MORE PICTURES.

It isn't my first disassembly for repair of equipment of this and earlier vintage, so it wasn't just me being careless. Things happen to labels sometimes, and it isn't anyone's fault, really.

Digital photos would have made the process quick and easy. Lack of them meant I had to trace each and every wire back to where it connected to somewhere else and then figure out which one that was on the schematic. It sucked. I got rather familiar with the chassis and the circuits, but it still sucked.

Save yourself a lot of anxiety when you flip that switch for the first time. Photos.

I do hope for your sake, however, that it is simply the fuse and you aren't put through that mill. I truly do.

Dave

You are correct. I made the mistake of trying to go by my memory and notes. The only way to have no or very little upscale movement of the S-meter on initial power on is to have the center pin of the SO-239 grounded and that is typically accomplished thru a grounding antenna switch.

If rig is left in Dummy load positions and AGC in Fast will still get some upscale deflection perhaps as much as 3/4, but wont deflect hard against the stop. In Slow much less pronounced movement. Each model behaves slightly different in that regard.

So if I had a TS820 in the operating position I would always have the antenna switched to grounding position when not in use. I use Alpha Delta switches and they also have built in arc gap and I have coaxial Transi-trap arc gaps outside in my coax entry panel.

Yes my operating practice is to leave AGC in Slow position as I work more SSB than CW and I also leave meter in ALC position as starting point for loading the rig. After peaking the Drive I place meter in IP and generally leave it there as I load with external wattmeter. This allows me to load to max RF output at same time monitor Ip to ensure not exceeding max plate current. I have a peak reading wattmeter so dont need to use the ALC position to properly set the mic gain although from time to time I will switch it back to ALC position in SSB mode.

Sorry for the mistake. I presently have the RF board out of my personal TS820 and cant check what I am reporting, but have not seen a KW hybrid yet that can not prevent banging the needle violently against peg by making sure the antenna input is grounded and to reduce it significantly by placing it on the dummy load.

Whole reason that it pegs is a race between the AGC bus voltage coming up from zero volts and AGC amp transistor driving it down due to off air noise seen by the AGC detector diodes on initial power on. AGC bus line comes up very fast as 9vdc regulator and RF-1 come hot. However off air noise when antenna is connected will be detected instantly and AGC amp will be turned on pulling down the bus voltage. "Dead" AGC bus will be seen by meter FET and meter driver transistor will produce greater than 0.40vdc output voltage which will put indicator on the peg or stop very hard.

So my advice stands to place rig on grounded antenna switch position when not in use and not have to remember to switch AGC to "safe" position. No point in needlessly exercising a switch that is not easy to come by and not easy to install and affords no ESD protection.

Again sorry for the mistake.

Terry K9TW

Topic: 47595 Message: 47602

Dave:

I was thinking about my rig and forgot I had customers TS820 here that is awaiting parts to repair the PA cage. Got the PA cage torn apart but can power it on after getting anode caps in the clear.

Connected it thru antenna switch and powered it on and you are 100% Correct and I am flat Wrong.

With the antenna switch grounded still get S-meter needle against the peg in Fast AGC position. Perhaps not as violently but still against the stop.

So as you point out only way to prevent this is to leave AGC switch in Slow position.

I would still leave antenna switch in ground position to protect against ESD.

Will look at schematic to see what is going on. Must be a knot in the line from RF-1 to the AGC bus! Only way to peg the meter is to have very low AGC bus voltage on power on combined with charging the AGC time constant caps. I dont think the AGC time constant caps are that much different between the models, but I dont know for sure. Pretty familiar with them in the TS530/TS830 rigs (and will find differences depending on rigs serial number).

Gives me something to do after I wash out the taste of that humble pie! .

My bad. I think I've got it. I'm used to dealing with some forms of compression/level limiting under the acronym ALC (Automatic Level Control). As I understand you to say, ALC is for compression/limiting of the transmitted signal where as AGC (Automatic Gain Control) is for the receive signal. I've still a bit to learn about this. I probably meant to say AGC as I was seeing a downward movement of the meter in response to an increase in level of the received signal. This is a problem I had understanding the nomanclature in the manual for the panel meter as it was extremely brief and limited in scope for it's operation/usage.

OK! I feel like I've finally got this figured out and at this point I feel like there may not be a problem at all, just my fears over this radio not being in good shape for the price I paid (I got it for a bit less than other examples available on EBay, including ones that had known issues). I initially contacted an old Ham buddy of mine on how to check this radio out once I got it in. His instructions for setting up the radio and checking the receive section were spot on with one exception; He told me to set the RF gain at "6" on the knob before turning it on. This caused the panel meter to deflect to full scale where I expected a low value with no signal present and rising upon the presence of a signal as it should. The old photostat copy of the manual I had was blurred, almost blank in some places and I missed a key piece of information upon reading it. That was to set the RF gain control "Full Clockwise/Maximum Value" under normal conditions in order for the S-Meter to properly read receive signal strength values. Taking the advice of one of the previous posters in this thread in getting a better copy of the manual in PDF format, I was able to find this information under section # 4.5 "RF GAIN" which that page was further down in the manual and missing in my copy along with a couple of other pages. Without reading this and catching it in the advice from "Terry K9TW" as to what the meter was actually reading; "voltage on the AGC bus" instead of an analog 'VU" type voltage generated from the presence of an audio signal as I'm used to, I never would have figured it out. I appreciate all the advice given here and from Terry in particular. I also feel like a dunce for inducing all this wasted bandwidth when if I had sought out better information in the first place it wouldn't have happened. If it's any consolation, I did learn quite a bit from this conversation.

Major 73's for all here!

James

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

James

For #2 what I was trying to say is it would be technically possible to have the HV position read in Rx mode, but little would be gained by it as the final tube anode voltage is not used for anything in receive mode. You need to know if it is available in TX mode and what level it is with no RF drive and with RF drive. So if you think about it you should not expect any indication in the HV meter position in Rx mode.

James:

Not complaining but that would have been nice bit of info in your original post!

No problem the ALC and AGC work differently in the KW hybrids from what most people are use to. It is a little hard to keep straight in your head. Both are very high impedance busses or rails that supply a DC control voltage to gate 2 of dual gate mosfets that are used in the IF and RF gain controlled stages.

Nominal voltage depending on model is 3.2vdc to 3.6vdc supplied by the AVR board and set by RF-1 trimmer pot. At some point you should check output of your AVR to ensure you have 9.0vdc and 3.5vdc.

At this level of control voltage the AGC and ALC amps are turned on to max gain. When you turn RF gain pot down you are simply are reducing the bus voltage which in turn lowers the gain of the mosfet amps. When the bus voltage goes down the S-meter (in Rx) and the ALC meter (in TX) goes up scale. This is confusing point for some. They use a FET based voltmeter so that the bus doesnt see the gate of the FET and is not pulled down trying to monitor the bus voltage.

Other way as Mike W5RKL reported is to receive the Marker signal or off air signals and the AGC detector diodes on the IF board will turn on the AGC amp transistor. This transistor collector is hanging on to the AGC bus and since it is fed by a 2.2 meg resistor it is very high Z and when the transistor is biased on it lowers the AGC bus in response to the detection of the off air signals.

There are some subtleties like -6vdc back bias to set AGC threshold and AGC fast and slow positions that select different RC time constants and of course a AGC off that uses -6vdc to hold off the AGC amp transistor.

RF pot gain is there so you dont have to listen to back ground noise when copying strong signals like on 80 or 40. Just run it back to comfortable listening level. Can also turn on the RF attenuator.

Have fun

Terry K9TW

Terry,

Due to this discussion, I've now connected ANT2 on my AT-230 to ground.
That will be my OFF protection against (small)ESD.

Your description of the race between the opposing forces is excellent and hopefully will encourage others to think it through.

Our fragile uA meters appreciate your patience!

Thanks for the continued guidance,
Dave f4eyk

47609. KENWOOD HYBRID NET UPDATE (February 8, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-09 20:04:41 UTC
From: Mark Gilger
Topic: 47609 Message: 47609

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday 40 meter net had 22 stations checking in under good band conditions. There were no new stations checking in. We had the following number of radios checking in.

5 running TS-520(x)
1 running TS-530(x)
4 running TS-820(x)
4 running TS-830S

I was running my TS-940s with an L4B amplifier.

The Sunday 20 meter net we had 25 check-in under good band conditions. There were 10 no new stations checking in today, VA3IED, NR9O, KF7RCE, KG7DPK, KJ4BPH, KB9LUQ, KK6FXK, AND N0RGJ. We had the following number of radios.

3 running TS-520(x)
1 running TS-530(x)
6 running TS-820(x)
2 running TS-830S

I was running my TS-820/R-820 twins with an L4B amplifier.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email.

Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 41, Sunday☐s total = 37 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Marcio:

You are not alone. No big deal. If you call or write Ken and talk to him he most likely wont admit to anything one way or the other. I have looked him in the eye and all I can say is you can tell a lot about how factual something is when you can see facial expressions.

OK just curious about the serial number. I kind of try to keep a list of serial numbers and years rigs were purchased and best if the person can produce the original invoice or a copy of it. More than one opinion when the first Gold Emblem was sold. I am still not 100% certain . You will find people have installed the gold emblem VFOs in early 1 million series rigs. I try to avoid the 1 million series 830s.

Not a lot of changes as you go up in the years but there are some. I have been wanting a pristine 6 or 7 million series, but dont want to have to mortgage the house! I own a 2 mil and 4 mil full filtered golds that I installed the filters including changing out the Murata K5 for the K12 (not any real noticeable change to the ear).

Only advice I can give is be very careful about installing any of the mods for the TS830 from any source. Come here and ask for an opinion before you do that.

Enjoy your treasure. Hopefully it will provide you with many hours of trouble free enjoyment.

Terry K9TW

47612. Re: [TS-520_820_530_830] RE: Meter Problem with Kenwood TS-820S : pegging meter at power on

Yes only other thing you can do to protect against ESD would be to disconnect the coax off back of rig. However you still have the station safety ground and power line ground and if strike is close enough you can have what is called ground potential rise.

So really only fool proof way is to unplug from the ac power, remove the antenna, and the chassis ground, and put in box and store in your closet. My luck house would burn down!

Unplugging from the AC power and grounding the SO-239 should be sufficient but lightning follows no rules. I turn off master switch but do not unplug from the line.

If I am home and lightning is near by I have unscrewed the coax even with my grounding antenna switches and coaxial arc gaps. It looks kind of silly to see a coax cable stuffed in to a glass jar on the bench!

Some fellows go outside and disconnect and throw the coax into the yard!

By the way I took a quick look at the AGC circuits on the 820 and the 830 and some differences. They both use a dual time constant circuit with a capacitor in parallel with resistor and that capacitor on the 820 is a .01uf and on the 830 it varies from .022 to .33 uf. Both use same 2.2 meg to feed the bus. Biggest difference is the 820 has a fast switching diode in RFG line. They are doing that to try to get the meter indication not to drift up or down scale after you move the RF gain pot.

With the TS830 depending on whether in Slow or Fast AGC when you move the RF gain pot there will be overshoot. Either slow drift up or drift down scale. This annoys some operators who want to set the meter to say 10 over. They have to adjust the pot twice. Just a little nuisance. Try it with your TS820 and I think it will not have any drift or very little but cant remember how it behaves in Fast or Slow.

Other than that a quick look didnt reveal to me a reason why the TS820 meter behaves different that a TS830 on initial turn on with the SO-239 grounded. I am just glad that my 830 does not bang hard against the peg when SO-239 is grounded. I just have to remember to power on and then switch the antenna switch to what ever antenna or dummy load I will use.

I am selling my VFO-120 remote VFO.
It is in excellent operating condition, and come with the connection cable.
The VFO was originally purchased for my TS-130SE, but when I sold the 130, I kept the VFO to use with my TS-830S where it served me well. The 830S is presently in storage as a backup rig, and I may end up selling it too so the VFO is for sale.

There are no boxes, or manual, but that can be downloaded off the internet.

The price is 135.00 shipped to the lower 48 via USPS, and I prefer PayPal.
I will give it a few days before listing it on QTH.

Well, I did say I hoped it was the fuse, at least twice in there. Here is the last one:

>> I do hope for your sake, however, that it is simply the fuse and you
>> aren't put through that mill. I truly do.

You weren't. Lucky you, be happy. <-;

Because I am. I'm quite happy that your fuse fused rather than your diodes. I hope nobody ever has to go through that same goat-rodeo. First 'magic smoke-out' was a loose case screw the previous owner had let rattle around in there, and which when they transported it to me had wedged somewhere that it could short one of the HV lines onto the output of the 14V power section. Poof. Smells nasty. Fuse is still intact, and yes Terry, I checked, both of them are the "right" ones.

Next time I missed a lick somehow, still don't know what happened, when I plugged the digital display into the back of the rig and flipped the main power. Same section of the rectifier board, gone AWOL in a puff of nasty smoke. Copper traces MIA presumed KIA. Just -gone- and nothing left but 4 cracked-in-half diodes and a bit of carbon on the bottom of the board where the copper used to hang out.

After the second melted rectifier board, I still haven't put that digital display back on the aux output on the back of the rig. I power it from a bench supply instead. It doesn't draw more power than it should, it's a current-limited bench supply and the -5 pulls less than one ampere total, even counting inrush. I've got the current limit run down to the 1-amp mark, and the meters never show it getting to the 1-amp mark either.

But I'm still NOT going to put it on the rig.

Twice I had to rebuild that rectifier board. I even made a mask from the picture of the board on the pdf files, printed it in the heaviest toner thickness my old HP laserjet 4 will produce, ironed it onto a clad piece of PC board, and etched a new one.

I don't wish to do it all a third time.

Drilled it, populated it, soldered it all down, connected it to the transformer inputs, checked the outputs (all good), but was too chicken ever to put the wires down on the outputs. I still have it, for a spare if I ever get really adventurous.

(I had gotten a pull board from a list member, and put that one in instead, and found out that there were differences in various boards that were NOT reflected in changed model numbers. Missing parts and circuits, such as the side-tone bias, that had to be hand-wired in with parts hanging off at odd angles.)

So, again, felicitations to you, and posthumous congratulations to a valiant and selfless fuse, that did it's duty and gave the ultimate sacrifice any component can make for it's circuitry.

(Yeah, I'm often quite a weisenheimer. Your point?)

Well I know where there is brand new still in shop (business closed) he still wants $A1250.00, $3200 for TL922 etc. It will be staying there for a long time at those prices of until owner turn SK and equip goes to auction. Along with some nice other stuff, when I went there I cleaned it off and covered it with plastic cover, couldnt see any components through the grill for the amount of dust.

I just sold a completely restored, 830s original gold label for $A750.00, that included full paint restoration of covers, front panel full restoration, full HV parts, new relay etc. Was 1 million series, included original boxes, manual and small accessories back (unopened). This gold label never had the filters installed, got if from original owner with receipts.

Topic: 47621 Message: 47622

No but easy to pull and inspect. Not very likely there is foreign material involved.

Down power and remove the 4 metric allen head screws. If has never been removed these will have been locktited and if so suggest you back them off and run back and forth as you continue to back them out to clear the threads of the glue so you dont strip them.

As you pull the VFO away from front panel the travel will be limited by the red wires powering the lamps on each side. These are in silicone rubber boots that just slide in a U shaped slot on each side of VFO so just slide them forward and remove.

Pull VFO forward until the miniature molex connector on rear panel can be unplugged.

Now remove the 4 small shield can screws and the one larger shield can screw and slide the shield off. Notice if the aluminum shield tape has been removed and curling up or missing. If so you know VFO trimmers have been accessed previously. Not a big deal just nice to know.

You can now inspect the gear train.

After clearing the obstruction or repairing the gear train. I would lube the entire mechanism with Tri-FLow applied by artist brush. Also clean the air variable rotor shaft wiper with Deoxit and run thru its range. Can also loosen and gently reseat the PC board screws. Be careful working around the air variable and the tank coil. Some folks use denatured alcohol at this time to clean the PC board and blow off with canned air. I never find the board to have any accumulation of greasy dirt.

When you re-install the shield can be very careful not to cross thread the very small metric screws. If you get any resistance just back out and start over.

When you slide VFO back in and slip the pilot lamps back in to the slots on each side and then re-seat the VFO in the front panel be careful not to pinch the red power leads on each side. I have found them pinched and crushed flat.

When lubing the gear train easy access to apply to all the gears including the anti-back lash and pinions. There is no front bearing. It is bushed. I usually orient the VFO on encdand apply Tri-flow around the shaft to get some to run down in to the bushing area. Just dont go crazy applying the Tri-flow as it only takes a very lite coating.

I've found on radios that have been shipped in that if a cup or bowl isn't placed over the tuning dial they get pushed in against the vernier, creating a bind. I've also encountered dials that have loose screws, working their way into the vernier.
Often one of the 2 screws is loose at any one time.
You might check to see if one screw is loose and the other barely holding. The dial may be "walking" towards the radio causing it to bind slightly.
I've never had a VFO out of a TS-830 so I don't know if this even applies to them. Terry's reply is prolly more applicable.

Hey Terry,

Are you interested in SN's in general or just for tracking the "Golds"? I was curious about my SN so checked my non-Gold 830 and the SN is 6020066; I have the original invoice from AES in Las Vegas dtd 8/5/85...$801.28 out the door. No listing of options. Still haven't removed the covers but based on receiver performnace, it likely only has the SSB filter installed.

BTW, would you please divulge the filter combos you use in your Golds? I'm betting YK88S + Murata K12 for SSB, (tnx Terry, would never have got that one); YK88C and YG455C for CW (?).

Lastly, I'll gobble up a bit more bandwidth with this true tale of service:

There is another invoice in my paperwork from the Kenwood service center dtd 11/24/92:

Description of trouble: " 78 Neutralization. Danger. See letter (letter missing from the paperwork),.Unit vibrates, hums, and lights dim." HMMMM...Isn't that why we love our Kenwoods???? Whats not to like about vibration, humming and pulsating (apparently) dimming lights???? Just to keep things serious, the repair order shows Kenwood service "Installed two new 6146B's and a new plate choke." Their notes state: "Final amplifier tubes were shorted burning out cathode resistors and plate choke. Repaired all defective parts. C19 (AC line filter) broken, replaces, aligned radio."

Repair costs + shipping: $210.46 (for those of you currently servicing KW hybrids, is that about what you charge today?. :-)

73,

You might want to loosen the two screws holding
the VFO knob on, and move the know out just a
bit. Could have gotten jamed into the skirt and
that's what is causing the binding.

Good luck,
Mark, WB0IQK

I'm not sure who sent this email, as there was no name attached. Hum.

Anyway it reminds me that I'm looking for serial numbers and original date of purchase on any Kenwood HYBRID radios. I'm going to create a database and post it on my web site so based on the posted serial number and dates someone can tell the aprox. production date for their radio. It will look similar to what is posted for the Drake stuff http://wb4hfn.com/DRAKE/DrakeSNDatabase-P1.htm

Thanks,
Mark, WB0IQK

My Gold 830 (no extra filters by the way) serial number is 2,041,157 (my 530 is in the 1 million)
I can't believe yours is 6 million? Wow.
Mark mentioned about starting a registry for the hybrids. That would be interesting to do.

Dave, I am curious about how you restored the front panel. Your discussion of the use of acrylic thinner was a help. There doesn't seem to be much info on the do's and don'ts. It would be a great service if you would do a write-up for the files. I am particularly interested in how you tackled to switch labels. Do you know of any method other than silkscreen? Dale KS4NS

Chris:

The serial number info you supplied is the only info that is 100% accurate. I see lots of I think, I believe, if my recollection is correct etc. I will take all input I can get my hands on, but love it when can get the Serial number and original dated Invoice.

When Mark is up and running with his data base I will pass on what I have. I dont have a lot.

Jimmy WB2KNR has his info from his purchase of his 1st TS520. I suspect lots of those owners are out there.

Also this subject has been discussed many times on this forum and if you search on "serial number" should find previous discussions.

As to filters I recommend that you follow Kenwoods recommendation in the Owners Instruction manual around page 24 that has the table for the various optional cw filters. Look at the CW4 position and 500hz bandwidth. The two filters listed allows you to make best use of the VBT feature. If VBT osc aligned correctly can adjust pass band from approx 150hz to 500hz. I have these filters in both of my TS830s.

I missed the part that rig was just shipped to him and could have incurred a blow to the VFO knob?

I thought he said it was a recent new condition?

If the knob set screw was loose and knob worked way toward the VFO he should have started to hear the analog dial scraping at some point in the rotation long before it seized or seriously impeded the rotation. The analog dials typically dont run true and if not adjusted correctly will have an annoying rub at some point in the rotation.

No problem with telling him to loosen the knob allen screw and slide the knob back and try rotating or remove the knob and analog dial and clutch spring and washers and then see if he can turn the shaft by hand. Should be able to do so easily.

Make sure there are two washers. I commonly find that one has been lost. Also good time to take tooth brush and clean all the grooves in the grey analog dial ring. They get pretty cruddy. I just use mild dish washing soap and soft bristle tooth brush.

Dale,

Most of the time I can restore the front panel without too much fuss, just a time issue. However, if the writing around the various controls is heavily worn, then I go radical and completely strip the front panel back to bare metal. Any imperfections in the metal is usually filled, if it is a large foundry issue then I'll use motlen lead and sand back. The the normal priming, undercoat, about 9 ultra fine dry sprayed top coats, and 1 wet sprayed coat. Then I usually leave it for 10 days for the thinners to dry out of the paint. The latext mould goes over the top and then apply the white paint for letters, markings etc. After a week (subject to temp) I will then use 3 different buffing compounds. End result is factory standard facia. This is only if I can't get a real good front facia panel from Bob, KE5FTF, usually just the top edge is chipped \scratched, most important thing in this case is to use good quality painters tape so you dont get any bleed through and take plenty of time to mask.

When I buy any Kenwood hybrid I ask the seller to remove the vfo knob & bag it...
Also remove the feet & bag them....
You can have the old gal damaged if thinley bubble wrapped & floated in peanuts (shifts to bottom)...
Believe me I speak from experience as I have purchased over 100 + hybrids...
A seller will always tell you he knows how to pack... :)
The orginal Kenwood box & outer box is the best though...

Terry K9TW

A wealth of information. Thanks to all.
No noise prior to the binding, no scraping, no squeling.

I have read my accumulated documention and service manuals.
The only suggestion there was to lube with non-adhearing thin oil,
and then only sparingly.

The exploded drawings matched exactly what Terry has written.

Will order some "DeOxit" and fetch an artist brush for 'lite' lubing.
Had already , gently, removed the Knob, found the two washers & spring intact,
fingered the shaft with no luck in rotating it.

When the procedure begins, I will be careful with the small machine screws,
and go very sparingly on the lube.

When the DeOxit comes in , then I'll get back to this.
Will have to do with my old HW8 for a while.

Thank you all, Glen KK4LPG

Lou,

In regards to the lettering, I only do complete respray\brush of the front panels I restore. The problem is when trying to repair worn painted lettering, unless you do the entire panel, it sticks out like a sore thumb, been there done that. As the latext mould is a very tight fit, I can either spray, screen print or use a very small artist brush. I like the screen printing best, but spraying the letters does give a slightly higher profile. Having the latex moulding\screen is the secret, anyone can then apply paint, cost is prohibited on making moulds unless you have a friend in the industry, which I do and she is fantastic. When spraying, you have to spray dry otherwise the paint will build up on the edges and when the screen is removed it rips the paint. I know a VK2, who restores front panels for the Kenwood TL922, but it is expensive, $250 for replacement front panel with you sending in your worn ones.

Hi Bob:

I have gotten several parts rigs that way because the owner did not know how to pack after telling me that they did. I dont like getting them that way. No reason for it.

I dont understand how you can ship anything without double boxing that allows about 4 inches of crush zone on all 6 sides and the rig heavy bubble wrapped inside another box centered in that crush zone. I would also use double wall (275# test) packing boxes. YES it cost money for those materials. If you have UPS or Fed Ex do it you are looking at around $150 total.

It is sad to see thin cardboard box arrive with exposed rig hanging out of the broken and crushed corner of the box. I have boxes arrive that wont sit flat on floor as the bottoms have become convex from weight of the rig.

I dont want to have to spend my time re-packing customers radios so can be safely returned. Not what I signed up for.

Your advice is needed and appreciated.

I wish Ebay had a rating category for how well the seller packed the item you purchased. Means more to me than the cost or how quickly.

Glen

Let us know what you find as this is very unusual failure. I find them to be able to rotate 360 degrees more often as people remove the pinion shaft stop pin and pop off the movable plates insulating spacer/stop bar.(CB mod). Yes a lite coat of Tri-flow will make it operate silky smooth.

Dont lubricate the air variable rotor shaft wipers just clean both of them. On the front one it is important to use small artist brush or tip of a toothpick to apply drop of Deoxit as you risk washing out the ball and race lube if you spray at the wiper. These are nickel plated wipers and never see any green or black oxide on them. Can use a tooth pick and put a touch of grease in the ball and race at shaft end but not much access is available to it. Take a look at the rotor centering lock screw on the outboard end. It should be locked with white paint. Never seen one cracked. Do see this problem on the Plate Load air variable caps and if this screw backs out it allows the rotor to shift and the plates to rub.

Only other freaky thing would be for a lamp to have come out of its slot and lamp and leads lodged in the works? Not sure there would be enough slack for that to happen.

Your findings will be of interest to all who work on their own rigs.

Hello everyone,

I have an 830-S Gold w/SN 2010517.
It has the CW Filter YK-88C and the SSB Filter YK-88S1.
It does not have the CW Cristal Filter and it doesn't look like one has been removed, but then again...
I did not buy the radio new, so I can't tell for a fact whether it came w/the filter or not.

Fine Business.
Thank you for sharing your insight.

Will explore a little further, but really want the DeOxit liquid & brush in hand first.
Liquid touched with toothpick is great idea.
Spray spreads too much, and can not count the amount that reachs a part.

Yep, blow off the cap plates, but never touch.
My HW8 has VFO cap that was touched, and it is off plus/minus 3 KHz
as I tune across a band, comparing with Knwd digital readout.

Will check the rotor centering lock screw for white paint.
Ideally, no play should be on this shaft.

If anything is amiss, I will post to you in this group.

I wrote to Kenwood about this as I have heard to many stories on this subject. Here is the answer I got.
I called and asked permission to post this and Leo said OK.
Hello William,

Thank You for your e-mail.
There is no difference mechanically between the Kenwood TS-830S with the white lettering label, and the TS-830S with the gold lettering label under the main VFO knob. The gold was just a later version. There was also an optional Deluxe Gold VFO knob called the KB-1 that can be installed on the TS-830S.
Sincerely, Leo

Glen,

You said

"/*blow off the cap plates, but never touch*//*
//
*//*My HW8 has VFO cap that was touched. and it is off plus/minus 3 Khz"*/

I could be wrong but it appears you may be suggesting that simply touching the plates of the HW-8'a VFO's variable capacitor caused your HW-8's VFO output frequency to change by 3Khz. If that's true, I have to disagree with you.

Simply touching the plates of a VFO's variable capacitor with your finger or a brush during a cleaning process that does not cause the variable plates to bend or move more into or out of the fixed plates (plate moving more into or out of the fixed plates is referred to as meshing of the capacitor plates), will not result in a 3Khz change in the HW-8's VFO output frequency.

> My HW8 has VFO cap that was touched, and it is off plus/minus 3 KHz

"Touched" ?? Or mashed it in and bent a plate? If the plate was just touched it cannot have affected anything electrically. Now, if they BENT a plate or moved that one plate around on the shaft (further in than the rest, or further out) when whoever-it-was "touched" it, then there might be some changes.

I think I would look a little further afield than this for the source of the 3KHz you are seeing. Perhaps a realignment might be in order here? Check for a gnat stuck on one of the plates of the capacitor? Or maybe one of the coils in the circuit also has a shifted winding, weakened insulation or something like that. (If just one turn shorted, it might cause just about 3K of inaccuracy....)

I cannot come up with any causal relationship between simply touching (no bends) a capacitor plate and any change in circuit operation (once you remove the offending finger from the circuit, of course). Anyone who can explain this, since fingerprint oil won't account for it) please elaborate, the physicist in me wants to hear it.

Hello all, I need directions on how to R and R a heater switch on the 520S. The switch feels funky and when measuring the temp(hand held infrared meter) through the vent holes onto the glass of the tubes. The tubes show only about 70-73F after about 5-6 mins. of on in a 67F room. The schematic I have is difficult to read so I have not tried to measure voltage at the wire that should bring voltage to the tubes heaters.
Any help will be greatly appreciated.
Thanks, Jerry K4GEW

Jerry,

The filament voltage for the final and driver tubes originates from the Rectifier Unit's "12VAC" source. The driver tube, a 12BY7, has a 12VAC filament voltage but the 6146's have 6.3VAC filament voltage.

The 6146 filaments are wired in "series" with 12VAC applied to the front 6146 tube socket's pin 2. Pin 7 is the other end of the filament which is connected to the rear 6146 tube socket pin 2 and pin 7 on the rear 6146 tube socket is connected to the chassis (ground) to complete the filament circuit.

The final tube glass envelope will be somewhat warm but not hot as long as no current is flowing in the tube, meaning the final tubes are biased to cut off. Heat is produced in the tubes when current flows between the cathode and the screens and plates and this only occurs when the 520 is producing RF output in transmit.

Terry,
Nice article.
The mod to add lead shot inside the VFO 'spinner' could whack the rotor vanes in excess of 3 ounces at end of travel.
I'll stick with my lightweight plastic spinner just in case...

Dave:

Most of those side plates are missing. They are missing on both my 520's

The problem is they used some rather fragile plastic buttons to hold them on and when those break the panel no doubt disappears soon thereafter.

I could make replacement out of aluminum plate but I would first have to devise suitable fasteners. I am thinking about using some Dzus fasteners I have happen to have on hand but have had too much to do to work on it.

Good Luck!

Jerry,

First, the top and bottom covers along with the front panel must be removed in order to gain access to the paddle switches. The TS-520S service manual, page 35, shows how this is done.

Second, this is not a "RTFM" response so don't take it that way. It's unfortunate but quite often people/hams tend to take offense to people telling them to read the manuals. You cannot properly and safely service your TS-520S without reading the TS-520S service manual.

If you do not have the TS-520S service manual then you can download it free at

http://www.n6wk.com/kenwood/520S_Service.pdf

If you do not have a replacement for the HEATER paddle switch then contact Bob Mansker, ke5ftf at mail dot com, he may have one.

Ken sells the plastic replacement buttons for the side panel quite
cheap here;

http://www.k4eaa.com/parts.htm

I have a TS-520 with the side panel intact and would be willing to trace it
and send a copy.
I could trace it and scan it into a pdf and email it, but I would be afraid
the size may get off little in the process.
I will trace it on to a card stock of some kind.
*So, David, *n0dks
I will get a copy out to you by the end of week,
I have your address off QRZ.

Robert, WB5WSV
Do you want a copy of the traced panel to use as a template to make
one sent to you too?

Bob,

D1 thru D4 are used in the KW hybrid's Rectifier Unit's high voltage "voltage doubling" supply. If you do not understand how a voltage doubling supply works then I recommend taking some time and study the ARRL handbook chapter on power supplies.

Diodes D1 thru D4 are simple silicon diodes. They can be substituted using 1N4007s. If one or two of the diodes fail, replace "all 4" diodes with new diodes. Mouser sells them for "14 cents" each. Make sure when replacing them that you insert the "banded lead" in the correct hole. Normally the board's "silk screening" has a wide band on the end of the diode silk screen that indicates the "banded lead" hole. If you install the diodes backwards you can damage the HV supply, including the two HV filter capacitors so pay attention when replacing the diodes!!

Bob

There is nothing special about a V08J diode. A standard 1000piv 1amp 1N4007 silicon rectifier will work just fine. A NTE-125 is a good sub. Just have to make sure that any sub you use the lead diameter is not too large for the hole.

If no electronics store can find them on ebay all the time.

47666. 6146 Arc Over Protection Mods

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-12 15:20:25 UTC
From: <wagstw46@...>
Topic: 47666 Message: 47666

William Adams WD8OSJ has revised the connections of the type OY glitch resistors in his TS830 after reviewing pictures of my installation. He was able to pull up enough slack in the translucent (white) 900vdc anode supply lead to the PA cage to place the glitch resistors in series with this lead rather than placing the resistors in the output of the HV filter bank. I did not try to pull up slack and was satisfied that I had the resistors at the source of the greatest joule contribution.

Bills change allows the resistors to limit the fault current contribution of the rectifier diodes as well as the filter bank.
He has a nice picture of his installation. Just make sure you open the PA cage and look at the lead where it terminates on the high voltage terminal block near base of the small VHF plate choke to ensure not pulling hard on this connection. If it is being stressed strip down a piece of RG8X or RG58 to obtain a long length of the center conductor to serve as replacement HV lead to replace the factory length.

Also do not be tempted to place back to back diodes across your meter in lieu of the 3 series diodes across the cathode meter shunt resistors. That form of protection will protect the meter movement, but will not prevent the cathode resistors from popping open. Our goal is to protect the meter and not have to repeatedly replace blown resistors with risk of eventually lifting a foil. With the 3 series diodes across the cathode resistors meter is protected and cathode resistors should never pop open and glitch resistor should help the diodes buy some time to allow slower acting primary fuse to clear the fault. It is still possible for the diodes to pop open but less likely with the glitch resistor and if they do easier to change than the cathode resistors and no damage to the final board traces and pads.

Good work Bill.

Terry K9TW

Terry,
Well, if placed in the translucent anode wire run (past the rectifier board), if there's a problem with the glitch resistors (like one would blow), you will not sense a problem on the HV meter scale, and continue on and blow the 6146's screen? Its always something isn't it?
If you break the anode wire, and place them there, I would jacket the resistors with some teflon tubing.

Mike, thanks for both the replies. I saw that in the SM but was concerned there was more to it like meter removal and so on. I didn't want to just start pulling things apart and hope I was doing it right.
I do not take your RTFM as a shot at all. rather a statement of where to start.
In the SM on page 44 it shows the voltage levels in the transmit section. Would it be reasonable to assume(I do know what that could mean) that if I took the voltage measurements at TP1 and TP2 I could use the results to narrow down the area to concentrate on? Another observation where is TP3? And to be sure I don't do it incorrectly... I have a Fluke DVOM(10M ohms) and the Fluke RF probe. I ask do you know if this meets the requirement on "input capacitance of less than 3pF"? Also what is the symbol BM at the beginning of the diagram? Sorry for so many noobie questions, I'm just trying to get as much info as I can.
Thanks again, Jerry K4gew

Topic: 47666 Message: 47669

Jan: William did not physically move them to the 800 post on the HV rect board as there is no room.

They remain on the phenolic terminal strip as noted in my original picture.

I intentionally did not place them above the HV rect board as too close a spacing, didnt want to block access to the other components, and didnt want to heat shrink or lexan tube them and didnt want them contacting the bottom cover. At 250ma only talking about approx .0.6 watts so heat shrinking should not present a dissipation problem, but locating them at and above the HV rect board is not a good choice.

William mounted his exactly as I did on terminal strip at the HV filter caps and had enough HV lead to make connections there.

If anode supply opens I doubt you would ever sense it on the HV meter in time to save the Screens from over dissipation even if you monitored HV all the time which no one would commonly do to operate one of these rigs.
I did no capacitor dump testing of these OY surge resistors. The data sheet shows testing at 100 pulses of 70 joules. If I ever lose one of the OYs then I will scrap the idea. They are rated at 80 joules.

If anyone wants to mod their rig based on repeated 6146 tube failure and blown cathode resistors, the number one part of the mod I would recommend would be the 3 series diodes across the cathode meter shunts. That alone should prevent the resistors from opening and limit the meter circuit to seeing a max of 2.1 vdc which is just slightly greater than the 1.75vdc it is designed for at 350ma indication.

I only installed the glitch resistors to try to prevent blowing the diodes and buy some time to allow the transformer primary fuse to blow.

Jerry,

Mike-w5rkl makes valid points. The final tubes(when heater on) will just sit there..with the heater
filament glowing..... the driver tube...more than likely will be hotter. Put some RF drive to a(properly) tuned up final section...and I guarantee the temps will rise!

As far as the heater switch goes...it may feel "sloppy" because one of the little fingers that holds the paddle to the switch itself is broken...common, failure of the switch itself....un-common. You can obtain replacements.

Anyone try a K1EL K42 keyer on your TS-830S?? Any special way to cable it?

As per this groups rules/policies...your posts/msgs are
REQUIRED to be signed (email header does not count)with name & call(if any).
Approval of this msg/post done as a courtesy.

Steven,

Based on reviewing the K42 keyer schematic, which you can download free at the following link:

http://k1el.tripod.com/files/K42assy_C.pdf

the K42 keyer output keying circuit uses an AQW210EH opto switch chip for PTT control and CW keying. The AQW210EH has 2 separate outputs, pins 5 and 6 as well as pins 7 and 8. You can see these outputs by reviewing the AQW210EH chip's data sheet.

According to the AQW210EH data sheet the chip's keying voltage specification appears to be "350V" at "120ma".

You can measure the CW key's voltage by simply plugging a 1/4" mono plug into the CW socket then use a DC volt meter, RED lead connected to the TIP and the BLACK lead connected to the SLEEVE (ground), and note the DC voltage on the meter.

http://pdf1.alldatasheet.com/datasheet-pdf/view/141092/NAIS/AQW210EH.html

You can test the keyer with the KW hybrid by performing the following:

1. Set SEND switch "DOWN" so the transmitter is NOT keyed
2. Set VOX to "OFF"
3. Set Mode switch to CW

Plug the keyer's 1/4" plug into the KW hybrid's rear panel's CW key socket. If you hear a constant CW side tone then simply reverse the wiring to the 1/4" plug, i.e.,move the wire from the plug's TIP to the plug's SLEEVE and the wire from the plug's SLEEVE to plug's TIP and repeat the test.

Mike,
It's always good procedure to keep both of those
switch in the ON position 100% of the time. The
older the radio gets, the more chance there is
for a failure. Plug the radio into a remote power
strip and turn it on/off via that switch. Easier
to replace the power strip than the switches inside of the radio.

Mark:

I will ask Bill to send you a new picture of the glitch resistor installation. The diode string and MOVs pictures are OK. Anyone who installed the glitch resistors at the output of the filter bank are OK and no need for concern. After they see what Bill did they can decide if they want to make the change. No jeopardy or sense of urgency to do anything at all.

I am working on tweaking the Low RF Drive Troubleshooting and how to perform the RX Level Diagrams white papers. Joe pulled them down for me today and I will send back to him and you. Should have them done by this week end.

Jan:
William did not physically move them to the 800 post on the HV rect board as there is no room.
They remain on the phenolic terminal strip as noted in my original picture.
I intentionally did not place them above the HV rect board as too close a spacing, didnt want to block access to the other components, and didnt want to heat shrink or lexan tube them and didnt want them contacting the bottom cover. At 250ma only talking about approx .0.6 watts so heat shrinking should not present a dissipation problem, but locating them at and above the HV rect board is not a good choice.

William mounted his exactly as I did on terminal strip at the HV filter caps and had enough HV lead to make connections there.

If anode supply opens I doubt you would ever sense it on the HV meter in time to save the Screens from over dissipation even if you monitored HV all the time which no one would commonly do to operate one of these rigs.
I did no capacitor dump testing of these OY surge resistors. The data sheet shows testing at 100 pulses of 70 joules. If I ever lose one of the OYs then I will scrap the idea. They are rated at 80 joules.

If anyone wants to mod their rig based on repeated 6146 tube failure and blown cathode resistors, the number one part of the mod I would recommend would be the 3 series diodes

across the cathode meter shunts. That alone should prevent the resistors from opening and limit the meter circuit to seeing a max of 2.1 vdc which is just slightly greater than the 1.75vdc it is designed for at 350ma indication.

I only installed the glitch resistors to try to prevent blowing the diodes and buy some time to allow the transformer primary fuse to blow.

Terry K9TW

Terry,
Well, if placed in the translucent anode wire run (past the rectifier board), if there's a problem with the glitch resistors (like one would blow), you will not sense a problem on the HV meter scale, and continue on and blow the 6146's screen? Its always something isn't it?
If you break the anode wire, and place them there, I would jacket the resistors with some teflon tubing.
Jan

wagstw46@... mailto:wagstw46@... wrote:

William Adams WD8OSJ has revised the connections of the type OY glitch resistors in his TS830 after reviewing pictures of my installation. He was able to pull up enough slack in the translucent (white) 900vdc anode supply lead to the PA cage to place the glitch resistors in series with this lead rather than placing the resistors in the output of the HV filter bank. I did not try to pull up slack and was satisfied that I had the resistors at the source of the greatest joule contribution.

Bills change allows the resistors to limit the fault current contribution of the rectifier diodes as well as the filter bank.
He has a nice picture of his installation. Just make sure you open the PA cage and look at the lead where it terminates on the high voltage terminal block near base of the small VHF plate choke to ensure not pulling hard on this connection. If it is being stressed strip down a piece of RG8X or RG58 to obtain a long length of the center conductor to serve as replacement HV lead to replace the factory length.

Also do not be tempted to place back to back diodes across your meter in lieu of the 3 series diodes across the cathode meter shunt resistors. That form of protection will protect the meter movement, but will not prevent the cathode resistors from popping open. Our goal is to protect the meter and not have to repeatedly replace blown resistors with risk of eventually lifting a foil. With the 3 series diodes across the cathode resistors meter is protected and cathode resistors should never pop open and glitch resistor should help the diodes buy some time to allow slower acting primary fuse to clear the fault. It is still possible for the diodes to pop open but less likely with the glitch resistor and if they do easier to change than the cathode resistors and no damage to the final board traces and pads.

Good work Bill.

47680. TS520S Loss of Rx

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-13 04:14:44 UTC
From: <pyrrus2003@...>
Topic: 47680 Message: 47680

This evening, I think I blew something in the Rx stage of my TS-520S. Tx power is fine, approximately 100 watts output. I had the radio on, but receiver turned all the way down, and I forgot it was on. I tuned up my HT-32 into the dummy load, and suddenly realized the TS-520S was on. Both radios share a selector switch into the antenna tuner, antenna and dummy load. I suspect that there is enough cross-position leakage to overload the receiver, and something blew. I have Rx, but it is down approximately 1% of what it should be-(e.g. 500 microvolts gives an S9 response where a 50 microvolt signal should respond at S9).

I will run the block diagram tomorrow evening, but any suggestions as to what to check would be welcome. I have a calibrated signal generator, a Simpson 260 multimeter, a HeathKit VTVM (unfortunately no RF probe, but I can build one) and a 100 mHz o'scope that unfortunately I don't know how to fully utilize.

Hello all.
My Kenwood TS-830 decided to die about 3 months ago and I have been to busy to concentrate on it or troubleshoot the problem. The problem is this and I would really like to know if anyone has seen this problem.
When I turn the radio on the LED numbers come on and then go dim very slowly. Then there is no receive or
transmit. If someone has seen this I could save some time by starting in the right place; power supply I'm pretty sure. Help would be greatly appreciated or I'll just have to wait until I get a round tu it.

John

You may have lost your L1 Ant Step Up transformer. Do you have WWV?

Try injecting at RFG terminal instead of ANT terminal. If good at RFG then most likely have lost L1. If still low then may have lost Q3 RF amp dual gate mosfet.

Can post on here and ask if anyone has a parts board to harvest a good L1 and if not then will have to rewind it or buy a board from Bob Mansker. .

Some of you may not know George Du Mond, K0GWD, but George was a KW hybrid group member for many years and owner of a KW TS-530 and TS-830. George passed away on February 9th, 2014 at his home with his family by his side.

I knew and was friends with George for years, helping him fix his TS-830 and his Swan 250 six meter transceiver. He wasn't a very active group member but he did read all the messages almost daily until his health kept him from those things. I will miss him but I know that he is in God's kingdom now.

Alan: Appreciate the vote of confidence but lets not celebrate yet. Could also be high resistance contact in the mini-din switch in the remote VFO jack on rear panel and in rare cases maybe bad transformer in the DC to DC converter on the counter display board or.....?????

It sounds like slow loss of VFO input to the PLL board so exercising the FIX is an easy first place to check. Of course getting any appreciable amount of deoxit to it is not an easy feat.

47691. 6146 Tube Arc Over Protection

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-13 17:36:59 UTC
From: <wagstw46@...>
Topic: 47691 Message: 47691

Well seems much confusion about the protection mod that Mark has posted on Ron WB4HFN site. Here is my original basis.

1. Prevent cathode resistors from popping open when 6146 arcs over from anode to beam plates (cathode) by shunting them with 3 series connected silicon diodes.
2. Protect the panel meter during arc over event by limiting maximum voltage across the meter and its series multiplier to approx 2vdc.
3. Protect the panel meter after the arc over event due to tube open cathode potential rise.

I had NO thought to limiting damage to the tubes or the power supply components as I had not witnessed any. Only problem I have seen with the tubes is that they may not hold off high enough anode to cathode voltage during a Hi pot test performed after an arc over event. Never seen any internal element damage. Only time I have seen element damage was during thermal runaway due to loss of operating bias. This is a very different type of event than tube arc over and usually results in the finals being destroyed as elements sag and short or melt holes in the plates or even suck in the glass envelope.

My goal was NOT to protect the tubes, the HV filter bank, the voltage doubler rectifiers, or the power transformer. None of these components in my experience are typically damaged during an arc over event. In fact, many owners replace the blown cathode resistors and re-power using the same 6146 tubes with no repeat events. While others almost immediately incur a repeat event (more my experience). There is no doubt that the event is stressful on the power supply components, but it is a very rapid event as evidenced by the violent nature the cathode resistors fail.

I installed the glitch resistor to limit the current that the 3 series diodes would have to handle. I did not want them to pop open. In doing so I may have slowed down the event and it is possible that the power supply components may now incur damage in the time it takes for the slower acting fuse to blow and clear the fault.

I have no evidence to support this concern. Just wanted anyone who is contemplating this mod to be aware that the fix may result in transferring the weak link elsewhere in the scheme.

I kind of wish now that I had not suggested or allowed Mark to publish. None of this is original design. I have previously mentioned that Tom W8JI helped me with the diode clamp and glitch resistor and I borrowed from the work of Ian White for the screen grid MOVs. Not much original work in linear amp design and protection schemes. Just the application of it.

So this post is to make sure that anyone contemplating this mod understands that I cannot guarantee that the "fix" will not introduce jeopardy elsewhere in the scheme. All I can tell you is that I have the mod as shown in Marks Technical Bulletin installed in my personal TS520, TS820 and two TS830S. I have also installed in probably more than 20 customer rigs and to date no blown cathode resistors or ill effects in my personal rigs and no reports of power supply damage from my customers.

I have nothing more to add on this topic on the forum. Suggest we take it off the forum.

Terry
K9TW.

Thanks for your response Terry.

Yes, I do have WWV, and a good strong signal it is. I haven't had an opportunity to try injecting a signal at the RFG terminal; I assume it is the one on the RF Board near the middle air variable capacitor. If I also assume the L1 you reference is also on the RF Board, the parts list shows it as a 470 microHenry ferri-inductor. My Mouser catalog shows a 470 microHenry inductor as looking like a pancake wound coil over a small ferrite rod - is this what L1 looks like, or is it located somewhere other than on the RF Board?

I guess my mistake qualifies as the dumba** screwup of the week.

Guys,
I'm only interested in serial numbers if we know
the date it was bought. Sometimes the original
owner wrote his serial number and date on the
front or back cover of his operating manual. I
have one like that. Or you might have been the
original purchaser. So for now, that's what I'm
looking for. Eventually when we get enough
numbers, a person can look and pretty well
determine what year his radio was made, at least
that's my hope if we get enough data points.

Thanks,
Mark, WB0IQK

No L1 is not a choke. The L1 I am talking about can be seen on the schematic if you look at the ANT terminal. You will see couple of 8.830 wave traps and then L1 step up transformer. It is on the Ant Coil Unit board below the RF board and is labeled as 1.9 mhz. Q3 RF amp is on the RF board.

The fact that you do receive WWV means that the switching diode and Q5 rf amp were not hurt by accidental transmit RF. Still could have lost L1 and/or Q3. You can also jumper center conductor from coax feed line from antenna to RFG terminal or to the solder lug of VC-2 air variable capacitor is easy to access.

You are not the first person to ever inject Transmit RF into front end of a rig. Easy to do. Some people use patch panels with BNC and SO-239 connectors on opposite ends and color coded tape on the patch cable ends etc to prevent this kind of event. Most antenna switches should have enough isolation at 100 watt power levels to prevent this from happening. Can be measured but wont go in to that here.

I meant a PL-259 on end of the patch cord opposite the BNC end and not a SO-239. Dont see patch panels much anymore. Just something to think about as it is darned near fool proof unless you put adapters on each end and defeat the different connectors.

Look at all the pictures here from beginning to end. Kind of fun.

From: Greg Lamey
Topic: 47704 Message: 47704

I have a DG5 that is driving me round the twist, and I suspect I am no orphan. One of the remedies I have read about is placing conductors through the through holes which are unreliable. Some of the DG5 through holes are under various ICs. Is it necessary then to unsolder each IC hiding a through hole to gain access to both sides of the hole?

I can not believe the DG5 is from the same manufacturer as the 520. One goes forever and the other is beset with intermittent faults.

I have got this display to read correctly on the 3.5meg band, but silly numbers on other bands.
all advice appreciated.

kind regards Greg

Before you go the long route of fixing every plated through hole, I suggest you re-solder the components around the HET input circuits. This has proven to be most troublesom on the DG-5's I repair. No guarentee this will fix it, but its where I usually start when I see those symptoms. Another thought, use short jumper cables and a good quality one for the HET input. This is a very low level signal and is easily attenuated.

Good Luck

Bill: Unfortunately as you know not easy to access the test points on the Counter Mixer board.

One thing you can check with unit in place is to make sure that the 21mhz low pass filter is getting its diode switching voltage. The bandswitch supplies 9vdc to turn on the filter switching diodes D5/D6 via B3. You can read B3 (pin 10 green wire) from bottom side at the 17 pin molex connector. Voltage will be less than 9.0vdc by approx 0.6vdc due to diode D19 on the PD board. Connect DMM to B3 pin and flip bandswitch on and off of 21 mhz position and you should see approx 8.4vdc come and go. This doesnt mean that the low pass filter switching diodes are really seeing it, but it tells you it is available at the molex connector and most likely the filter is being turned on to allow output. Not often that any of the Low Pass filter switching diodes fail.

Unfortunately not easy to access TP-5 or CIN on the Counter Mix board. At TP-5 you should see approx 200mv signal level.

There is no Het osc input to the Counter Mixer board on a TS-820S? I thought this was the rig in question? There is Carrier (CCR) from the IF board and VCO (CVC) from the PLL board. If you have set the Carrier Osc output level according to the Service manual you should be having other problems. The Carrier Osc level should be set to 300mv and not 50mv as directed. After Carrier Osc is set to 300mv then you can adjust the CCR level from the IF board by adjusting trimmer cap TC-1 (you can see it near Q17 on the schematic). Can measure the levels at CA2 and CCR on the IF Board at Molex Conn IF-5, but I like to measure it at the Counter Mixer Board.

CCR at Pin 7 should be approx 100mv to 150mv

CVC at Pin 1 should be approx 900mv

Unless you have adjusted the Carrier Osclillator levels to 50mv I doubt that CCR or CVC levels are a problem just effecting 21 mhz display.
Terry K9TW.

Hi Group. The 21 Mhz display issue for my 820S is solved thanks to Terry's great suggestion(s) and pointers!
I did a resistance check at the Counter Mixer pin 10 (B3) to D6, D5 on the 21 Mhz LPF.....open. L14 was open!! Solved!!
Thanks Terry.....your a champ!!

I'm the very proud, original owner of a TS-820, serial #641383, that I purchased in the Spring of 1978 from the Air Force Post Exchange in Weisbaden, while stationed in West Germany with the Army. I added the digital display and the optional CW filter a few months later. The following year I bought the VFO-820 (#640497) and the SP-820 (#661413). The AT-230 (#3010185) came next in 1980. The rig was so hot at the time that I thought this was the last rig I'd own. After some cap replacements and other service work along the way, the rig works as good as the day I excitedly brought it home.

Bill: That is a real unusual failure as the diode current is only approx 3ma?

If you had the board out might be interesting to measure DC voltage drop from TP-4 and TP-5 to chassis ground. This would be IR drop across current limiting resistors R20 and R26 3.3k ohm. My guess is would be something on the order of approx 7.5vdc if all is well.

Anyway good find.

Joe,

The TS-520 was the first in the series of 520s. It did not have 160 meters, came with the DC to DC converter standard, the dial was white, and the meter switch was on the right of the dial as an outer ring switch that is part of the LOAD control and the fixed (CH SELECT) crystal select switch (4 positions) was to the left of the dial (right of the meter), there was not attenuator switch, and JJY/WWV was a "push button" on the front panel.

The TS-520S was the second in the series of 520s. It had 160 meters, the DC to DC converter was an "optional" accessory, the dial was dark, and the meter switch was moved to the left of the dial. The fixed (CH SELECT) crystal select switch (4 positions) was moved to the right of the dial and made as an outer ring switch that is part of the LOAD control. The JJY/WWV band select was moved to the band switch, the "AUX" (receive only) position was added to the band switch, and the JJY/WWV Push Button switch became the RF ATT (RF ATTenuator) switch. The DX PULL ON switch was relabled "PROCESSOR PULL ON" and the 6146 final amplifier tube sockets were mounted on a PC board labled "FINAL UNIT X56-1220-00" rather than mounted to holes punched in the chassis with point to point wiring as they were in the TS-520.

The TS-520SE was the last of the TS-520 series. Not many changes between the TS-520S and TS-520SE. The HEATER switch was eliminated, replaced with a "WIDE/NAR" switch (the filaments were lite as soon as main power was turned on), and the TS-520SE was designed to operate on "120/240VAC" ONLY, no DC power option.

Yes, the TS-820 and TS-820S were a step up from the TS-520 series. The TS-820 and TS-820S were identical except for the digital display. Check with Bob Mansker, ke5ftf at mail dot com, he may have a digital display assembly and display tube for your TS-820.

Joe,

You asked what a partially working TS-520 would be priced at. That's not easy to do. What I or anyone else would price a partially working TS-520 may not be what you would price that same 520 at. It all depends on what a person is willing to pay.

For the 520 models the difference is mostly age, The 520SE replaced the 520S which replaced the 520. the 520SE has a builtin power supply but doesn't have the option of running on 12V. The 820 models are Deluxe versions of the same ideas. and the ts_#30 models have the WARC bands.

Subject: [TS-520_820_530_830] TS-830s "Silver Ring" around VFO knob, "mod check?"
To: TS-520_820_530_830@yahoogroups.com
Date: Sunday, February 16, 2014, 12:39 PM

Alright, folks. New owner of a TS-830s
here, in apparently good- enough- to-receive condition.
(After fixing some stuff mentioned below).
First question: There's a silver ring with
lines on it, around the VFO knob. What is it? Is spring
loaded, apparently, but doesn't seem to do anything. It
normally turns with the knob, or if I push it back (against
the spring) it can be stationary.

I can't for the life of me figure out what
it could be for other than aesthetics.
Question two: I'm curious about the county
of origin. This thing came wired for 220 US, but based on
the wiring, it did not come from the factory that way. The
power cord was in TERRIBLE condition (crunchy, exposed
copper), so I replaced it and rewired the transformer for
110 with the help of Freenode IRC ##hamradio.

Everything seems fine, but I'm wondering
WHY someone might have done this. I'm curious if the
thing is "tweaked" for a higher powerful output,
or had been adulterated in any other ways.

So, what should I be looking for in this rig,
especially I suppose in the PA stage, to see if it's
been meddled with?
Also, I assume this was US 'origin,'
but I don't ACTUALLY know that. Anything obvious that
would set it apart? (I don't know much about
international ham allocations).

Need to lay the 520 schematic next to the 520S and study the circuit differences. Take a look at Gen Board and RF board for starters. If I could only buy one of the 520 series it would be the 520S as it has better receiver front end. Better RX intermod and better 2 signal blocking characteristics mainly due to addition of a switched capacitive voltage divider that reduces signal level to 1st mixer on the lower bands and allows 10 meters to run hot. Too many differences to list all here.

Hi Craig:

Last ones I got from Bob Mansker.

I was looking at the NCH Tone generator contemplating purchase and one thing I dont see is what output level reference they use. My guess would be 0dBu = 0.775v, but I didnt see it mentioned anywhere. Do you know what it is?

When you used it to adjust the Carrier set point what dB level did you set if for to inject into your mic line? I would expect 7mv would be approx -41dB and 10mv would be approx -37.7dB? Did you measure the output level? My Leader Audio Gen has both dB and rms volts meter scales and it is pretty accurate, but I usually measure it with HP3400 and watch to make sure stays constant level as I move from 200hz to 3000hz.

The Leader is getting long in the tooth and thinking about going the lap top way. I realize output will be stepped and not as likely to be able to sweep the output frequency slowly either side of roll off point as you would with an analog gen. I assume can get 1 hz +/- steps? My guess is that continuous frequency change would be pretty fast rate and touchy and not as smooth as it is with vernier tuning on the analog generators?

OK to answer off the list.

Hello.

I just bought a VFO-230.

I am using it with my TS-830S.

When I am on for example 14.000MHz and the functions receive is on VFO the Display og the VFO-230 states 0.0 anf the TS-830S states 14.380.

Trying to change the main tuning of the VFO-220 until the VFO states L 900.0 the TS-830S states 14.280MHz...

Maybe the VFO needs to be calibrated, but how?

Any idea how to calibrate this unit?

Joe -
If you scan through Universal Radio...
http://www.universal-radio.com/catalog/hamhf/ts520.html
http://www.universal-radio.com/catalog/hamhf/ts520.html
http://www.universal-radio.com/catalog/hamhf/ts520s.html
http://www.universal-radio.com/catalog/hamhf/ts520s.html
http://www.universal-radio.com/catalog/hamhf/ts520se.html
http://www.universal-radio.com/catalog/hamhf/ts520se.html

... it might help. There are differences but in many cases they seem to be nuanced.

What's an RX but no TX 520 worth? As much as I can get for it on eBay! :-) I originally paid $315 for it, got back $100 when it arrived non-working, and put $79 in "new" tubes for it (driver and finals). I'm selling it for $255 (Start bid) so I'm still in the hole but I may break even if it gets bid up. For this radio, the fact that it's in good cosmetic shape and receives well, plus the replacement tubes had me set that value. For others it may be different, up or down. That's the best I can tell you.

Are there differences between the 820 and 520? I'm sure I'll get an argument but, for my usage, it still amounts to minor difference and major nuance. I got my TS-820s thinking I'd pair it with an R-820 but when I found out what the R-820 was going for these days I nearly crapped my pants. (Sorry for the imagery.) Kept the 820s anyway but got the T-599d and R-599d twins. Half the price of just the R-820.

Personally, I wanted a digital display for my 520 (the working one), looked at the DG-5 and all that it involved and then bought a DD-103 (http://www.electronicspecialtyproducts.com/dd103.html). Plugged it in to the VFO port and it miraculously worked right out the box (after about 5 minutes of adjustment from what has to be the worst user manual I've ever read --and you do NEED to read the manual). They're advertised for the 520 and 820 (and I presume that extends to the "s" versions but winter came upon me before I could play around). It's about $180 for the display and cable so it's price competitive with the.DG-1, Just not branded "Kenwood." (Letraset anyone? hihi)

Hoped some of that helped.

Man you cant be serious? Saying that the differences between a TS520 and TS820 are "nuances" of any kind is amazing. Kind of like a man saying the difference between a 1960 Chevy with carburetor and breaker point ignition and a 1990 Chevy with computer controlled fuel injection and pointless ignition are nuances. I like not having to "set the choke" or gum-out clean the choke or to have to replace points, rotor, condenser and plugs every 12000 miles not to mention leaps in improvement in cold start, drivability, fuel economy etc. About the only thing I miss is the sound of those secondaries opening on that 4 barrel carb!

I suppose you could say that comparing the physical size, front panel control layout, and feel of the planetary gear drive could be considered "nuances". After that in my book some real substantive differences from an operating, performance, and maintenance perspective.

The differences between a TS520 and TS820 are night and day if you are a student of the brand and a sophisticated operator.

1. Single conversion (quieter)
2. PLL (far fewer spurs and birdies that plague the TS520)
3. IF Shift (passband tuning is self explanatory in crowded band conditions)
4. RF Monitor (nice operator and maintenance aid)
5. True RF compressor (455 IF and not audio processing)
6. RF negative feedback (ok I will give you this one, but nice to have if you try to load in to an open not to mention cleaner output signal)
7. In some ways actually easier to troubleshoot and repair due to the as built config and layout. Less component density and more room with the terminal posts and wires moved off the boards. Other than the digital display issues and a very poor service manual a pretty easy rig to troubleshoot and align.

Nothing wrong with the TS520 (basic collins het osc conversion scheme copy). I started with one and still have one but seldom operate it. Best thing is to own all the KW hybrids at one time or another.

If you are contemplating buying a TS520 go ahead and do so and enjoy it. I hope with time you can progress right up thru the models to a full filtered TS-830. Only then will you be able to decide if you could keep and operate one which model that would be. Depends on if you are a contester, a dx chaser, a CW op as well as what your definition of quality is. One mans must have function or feature may well be another mans "nuance".

My interest is finding a basic HF radio, one I will clean up, repair any deficiencies I find and then put it in service as a loaner to new Generals. I have several low band verticals that are semi portable I loan as well.....

I try and support the local ham community, in any small way I can. Several years ago, I bought 10 Yeasu FT-5100's at a ham swap, that were broken. I was able to get 8 of them up and running again.....ALAS, they are all gone now....I gave them all to new techs to get them on the air...then one the local ham clubs had a J-Pole party and made VHF/UHF J-Poles, that we included with each radio 'give-a-way', All the materials and location to build them, were donated by a local plumbing company and cable and connectors donated by a contest station, here in Northwest.

Those were the days...Seriously, the days of true comadrieship in this hobby are long gone....I really believe the 'relaxing' of ticket requirements, are the reason. ie: No more code, dumping down of the tests, etc. Almost the same now as getting Citizen's Band license. :(

OK, off my soap box.....

HEH...this is gonna get interesting.....!!!

Terry...Maybe no more 'carb cleaning' the choke, etc., but on all the new, 'modren' F.I. systems, it is mandatory the MAF is pulled at least every 60k miles (Or when your mileage starts to deteriorate!) and cleaned..the ports all gum up and need to be soaked in carb cleaner for 30 minutes or so. BMW even had issues with the intake system that necessitated pulling the entire intake manifold and walnut shell blasting it, to clean out the gunk, none of which was under any warranty policy.

OK..back to radios.....As you have already read by now, my interest in this particular 520 is not for me....I have 2 820's, 1 an S and the other plain vanilla, but my main Tube radio I use are my Drakes. (R-4B, TX-4B, L-4B, etc. w/ all the accrudiments, MN2000, upgraded AC-4 power supplies, etc. (Yes I have two complete "B" sets including the amplifiers...)

But my main radio is my TS-2000X, the good old 'Shack In A Box!' pushing a 23 year old Henry 2KD Classic with a factory updated transformer. It can loaf all day long at 1300 watts out.....it is so clean and strong. I rarely, if ever, push it over 500 watts out..just not needed, even in a major pile-up.....the superb audio characteristics of the 2k, and the Henry, will blow through almost anything.

Every now and again, I dig out either of the two 820's and run them for a couple of days, just to keep them at tip top performance.

My only real issue with my Kenwood hybrids, is the VFO820 I got from Steve (I think it was) a couple of years ago. I lose weight trying to keep up with it until it warms up..that sucker drifts up a storm before it settles down and stabilizes...even then I have to keep 'touching' it up a bit, but that is minor..no more than from Donald Duck down to the Duck when he is hoarse. LOL. Some day I will get around to looking at the caps in it...but first, as I know very little about external VFO's, I will consult you guys about what to poke and prod...

I think I am seeing the same thing here in the Seattle area. Most interest is in VHF repeater activity. Very little interest tin the technical aspects of the hobby. The new people all want Plug and Play..

I've even noticed truckers (who used to use CB) using the local repeaters with out using any ID.

Sorry this has little to do with repairing Kenwood Hybrids.

47744. Dayton Hamvention 1st Ever Forum

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-17 16:29:25 UTC
From: Mark Gilger
Topic: 47744 Message: 47744

Jan, W8CBX is a active member of our Saturday Hybrid net on 40 meters. He's also a member of the Dayton club that puts on the Dayton Hamvention. Several weeks ago I put out a suggestion to our Hybrid Net group about how nice it would be to have a forum at Dayton. Jan took the ball and ran with it. He meet with the convention committee about getting us set up with a forum room.

Darn if they did not come through and give us one. That's great, but the bad thing is that it's Sunday, May 18, in room #2 from 10:30 - 11:30AM. Most of the guys I know are either already home on Sunday, or headed that way. myself included. Looks like I'll be there all 3 days this year. So if it's not too late to change your plans, we would love to see you at the Forum this year.

Very preliminary topic subjects that Jan and I discussed are:

1) History of the Legacy products TS-510 - TS-830's.
2) Resource help with Parts, Documentation presentation.
3) SDR integration into the Legacy line.
4) Rewinding TS-830s L41 coil
5) Questions and Answer session

After the first years forum is out of the way, the plans are to ask for a better time slot for Friday or Saturday. It's our opinion that we wouldn't have much chance asking for a better time slot without first getting this first one off the ground and showing interest enough to warrant a better spot. Maybe a full room standing room only would work....

So mark your calendars:

Sunday, May 18, in room #2 from 10:30 - 11:30AM

73's,
Mark, WB0IQK

Gentlemen,

If you want to discuss cars and why hams don't study for their licenses, please do it through private email. This group is not about those subjects but rather the group is about Kenwood TS-520, TS-820, TS-530, TS-830 and a few other Kenwood transmitter and receiver hybrids, not automobiles and helping other members with their hybrid problems.

I am also am seeing some members who are still not adding the message signature to the end of their messages! Each member who applied for and was approved as a member was sent a message outlining the simple rules of this group which includes the requirement for each member who posts messages on this group to add a signature at the end of the member's messages. If you do not know what the signature rules is then you need to read the message sent to you when your membership was approved! If you did not read the message sent to you when your membership was approved, you possibly deleted it, then you will have to log onto the group's homepage, go to the Files section, and read the message in the auto message folder!

47749. group policy/rules update

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-17 21:41:43 UTC
From: Joseph Stiles
Topic: 47749 Message: 47749

Greetings Group!

I hope we all made it through another Valentine's Day with our YL/XYL's or, OM's, as the case may be.

As promised earlier, the groups policies/rules have been updated. You should be able to view
the small change, in the files section under "auto text messages." If, for some reason, you can not
view it, let me know. All it deals with is the "signature(sig) lines" difficulty from a few weeks ago.
Also, several members who have seen fit to not abide by the group's policies/rules,
have been banned, claiming that they felt THEY did not have to PROPERLY identify themselves
according to the group's policies/rules because of their desire to remain
anonymous or, just did not want to do it.

The moderators and I, strive to keep this group "neutral," in as many aspects
as possible. We do however, realize that "opinions" vary. So, that being said,
let's move on, regard the policies/rules, respect others...and keep on with the
task of keeping these great rigs repaired and functioning for many years to come.

Thanks for your time, we now return you to the regular scheduled program.....

47751. TS-820 Driver shield

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-17 23:49:10 UTC
From: <dougc314@...>
Topic: 47751 Message: 47751

Hello, I'm new to amateur radio, but not electronics. After getting my ticket I decided to get a TS-820 because it's from the era of electronics that I really enjoy working with. Unfortunately my radio has suffered a bit of "unauthorized access", which I need to undo. One of the things that I noticed is a ground strap for what must be a missing shield for the driver tube. I have some shields, or could easily fabricate something from some brass, or even mu-metal, sheeting .but would appreciate it if somebody could describe the OEM shield. What I want to know is what portion of the tube is sleeved. It's probably the whole length, but I would like to be certain, as the sleeve might make the tube run hotter.

Thanks, Doug C.

47752. TS-820 HET crystal source

Yahoo group: TS-520_820_530_830 (2014)

From: <dougc314@...>
Topic: 47752 Message: 47752

Sadly, one of the most disappointing things I must undo to my recently acquired TS-820 is the fact that the 28 and 28.5 MHz HET crystals were replaced by crystals 1 MHz lower, for unmentionable reasons, I assume. Does anybody know of a source for the crystals? Back when I was designing crystal oscillators it was no big deal to specify a crystal and get prototype quantities. For product development the price wasn't an issue, but I would like to avoid a custom run if at all possible, just for repairing my radio, I know there are some on EBAY right now, if that's the going price, then I guess I'll try them on.

Regards, Doug C.

Doug,

I second Bob's recommendation. International Crystals is top notch. Expect to pay about $22 - $25 per crystal. Pricey? a bit...but you don't have to worry about them being off freq...or otherwise damaged...and their guarantee is excellent. Go to their web site and take a peek: www.icmfg.com You probably know why the crystals in question are 1 kHz low..CB HACK, aka "free banding" Take a very close look at the transformer and rectifier board wiring, and compare with schematic. If you see the "210" wire moved to the "300" post...that's to increase voltage to the final amplifier tubes screen. More volts...more power....bad idea!

Doug,

  The tube shield on the 12by7a driver, covers the whole tube, excluding the top...so it's just a cylinder...the long metal tang ground goes between the shield and the tube. Several members are running their rigs with no shield and have reported no ill effects.

  Also, I noticed that you have your "ticket." Congrats. So, in keeping with the groups policies/rules, you need to include your call with your name when signing posts.

Tnx

47756. TS-830s on e-pay

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-18 15:37:52 UTC
From: KB1TCD
Topic: 47756 Message: 47756

Hi all!

Went to e-pay last night and found three TS-830S radios.
One in "collector condition" for $1,250.00 (I am now making sure no one comes anywhere
near my radio...hi, hi)
One with starting bid at $500 and buy it now for $800 that stated the radio does AM and CW. I brought the AM part to the seller and he has now fixed it.
Seller wrote: "That description is what Ebay selected out of their 'catalog'. "
There is another for $450 and but it now for $700, also said AM and CW.
Leave it to e-pay...

BTW, I also have a Yaesu 897D and the audio is so poor compared to the 830S that I only use the Yaesu for 6m and digital...that much of a difference!

Hi Terry, et al,

Regarding the NCH Tone Generator software, I honestly do not know what the output level is and did not measure it. When adjusting the frequency response of the SSB filters in my TS-830S and TS-530S, I injected the generator's output into the radios' mic inputs through the Tigertronics SignaLink USB interface that I employ for digital modes, adjusting its output for a clean sounding signal. I have been getting complimentary transmit audio reports from both radios since -- including a report of "perfect response" from a fellow monitoring my signal on a scope. Therefore, I have left well enough alone and have not done any further investigation of the software's capability (which is largely undocumented by the makers).

Sweep tones (log or linear) can be generated in 1 Hz increments over any desired time period. Multiple tones can be generated simultaneously (useful for two-tone SSB testing, for instance). It's pretty nifty.
The software can be downloaded on a trial basis at http://www.nch.com.au/tonegen/index.html http://www.nch.com.au/tonegen/index.html and the purchase price is quite reasonable.

My next purchase is going to be the Elecraft XG3 RF Signal Source to replace the ancient and ailing AN/URM 25 generator I now use. I am also investigating PC based oscilloscopes; attemptng to find one that is both useful and affordable.

47760. TS-830S ALC glitch

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-18 19:59:16 UTC
From: <crgrbrts@...>
Topic: 47760 Message: 47760

Yesterday I finally got around to doing a rough and superficial alignment of my TS-830S using the simplified, no-test-instrument-needed sequence in the radio's user's manual. All went well. Well -- almost all went well until I re-introduced an anomaly that had been apparent before I began the extensive repair and refurbishing that has yielded an 830 that looks and performs as new. Almost.

On the first 50-75 KHz of 40 meters -- and only there -- ALC is glitchy. When in TUNE position, rotating the DRIVE control results in flaky ALC readings -- not a smooth response but rough readings with at least two peaks as if responding to a dirty control. Ultimately, output is normal and, as I said, this "scratchy" ALC metering occurs only on the low end of 40 meters.

One might suspect that the three DRIVE control variable cap sections are out of sync or suffering from uneven rotation caused by those pesky cracked nylon upper sprocket wheels. Yet, when the DRIVE control is rotated through the same arc on other bands, the glitch does not occur.

As I mentioned, we experienced this problem once before. I resolved it by peaking the transmit drive coil at a frequency of about 7.050 MHz rather than the specified 7.150 MHz, but that seems like a cheat. I'd like to get the radio performing "by the book."

Any ideas?

Oh, I have ordered a set of NR6C's reproduction drive control sprocket wheels and anxiously await their arrival. Perhaps Gregory's terrific replacements will somehow cure this unpleasantness. We shall see. I'll let you know.

Hello, my name is Leonard (WV3P). I have a 520s that has no receive. None of the bands work including wwv. So far here's what I've done. I've cleaned both relays, the VFO, and all the switches. That seemed to fix the marker which I can now hear. I also hear what I consider to be a white noise coming from the speaker. I can turn the volume up & down and that does work, but I can't receive any signals when hooked up to an antenna. Can you guys give me an idea of where to start troubleshooting this radio? I did use another radio to transmit a signal while my son tried to tune it in on the 520s. He said he could hear something on the receive, but no S-meter movement and the signal was very distorted. The transmitting antenna was approximately 50 ft from the 520. I'm not sure if that helps or not. I do have a signal generator, oscilloscope, frequency counter and voltmeter, but I've never done any real troubleshooting. Thanks for any help.

Yes, you will want to reduce power by using the CARRIER LVL adjustment to a level that your amplifier can use as not to overdrive.

I have a SB220 connected to my TS-830 and with excellent results. I adjust the output power of the TS-830 to abt 50 watts exciter power. This drive level provides an amplifier output of abt 550 watts. I also use an Ameritron ARB-704 as an interface to protect the transceiver.

Hope this helps, enjoy the hobby as I do.

Leonard,

Pull the relay and give the contacts a bit of a clean, I use filter paper and pure ethanol, it cleaned up like new. I did this to a 520 several weeks ago with similar issues. Also I pulled the octal plug from back and cleaned the corroded pins. Once back together it came back to life. A quick alignment and the owner has told me how extremely happy he is. I dont normally touch the 20 series, but this seemed to work

Yes you could set mic gain to 1000 to 1100 and then adjust the NCH level for approx 50 watts output so not likely then to overdrive the rigs mic input. I can measure the NCH output should I buy, but would like to know what reference they are using. I guess I am still on the fence about it versus buying a new arbitrary/function waveform generator (not cheap). I need to investigate other software similar to NCH or perhaps write to them to see if can get some more info.

Thanks

What kind of signal generator do you have? Do you know what output level you can set it to? If it is one with just a Low, Medium, High then set it to high and set any variable attenuator to max level and inject RF into the SO-239 connector on rear of rig. Do this on all bands and if S-meter pegs simply turn the level down to get meter back on scale. This is assuming that you know your generator has good output.

I would do this with VFO around 200 and the Drive control at 1200 and RF gain pot full CW.

Pull out the schematic and follow the off air signal path. You say you can hear the Marker since cleaning relays. Look at where Marker signal enters front end. If hearing Marker then you know that path is good. Now study the schematic and ask self how is the Marker path different than Off air signal path and what is in that path that could attenuate the signal? You should see three devices. RX ant switch, RF attenuator, and Xverter switch. This could end up being an easy fix.

I forgot to mention just be aware if you buy the XG-3 to replace your URM-25 that it has no variable output level attenuator. It has 4 switch selectable commonly used output levels. To use it to perform all the alignment steps in KW hybrid service manual you will need to use an external step attenutor with it. Elecraft and Hendricks both sell kits or you can homebrew one. Also to vary the output frequency you need to use your lap top. It does have enough switch positions that you can program in the the commonly used KW hybrid alignment frequencies ie 8.830mhz etc.

I use mine mostly at Hamfest to screen equipment I am interested in buying. Took it to Dayton and drove receivers and O-scopes etc with it. Small size makes it ideal for that.

I am not saying cant use as a bench RF sig gen just realize has limitations and you need to buy the USB cable for it. Lastly the sweep function is not very useful.

For another $50 - $75 can buy a refurbed Wavetek 3001 or 3002 or 1170/U off K8IFF Dennis near Detroit. He does a great job with these.

Thanks for the reply Dave. I pulled out both relays in the 520s, I cleaned them with deoxit which I sprayed on a small piece of paper that I pulled (carefully) between the contacts. That didn't help. I also sprayed deoxit on the 9 pin plug and pushed it in and out of the socket a couple of times. That did nothing either. I did notice that there seems to be for lack of a better way to put it, a kind of low pitched pulsing sound that comes out of the speaker. It has a very definite rhythm to it. The search goes on.

Hi Jose,
It is a fluke of eBay that anyone who lists an amateur transceiver will get it listed in the category of AM and CW even if it is not true like in the case of the three TS-830S units that are for sale. I sold a TS-830S (for parts or repair) a few months ago and I could not get that category corrected, so I had to add an explanation to correct it that it was for CW and SSB and there was no AM capability. Good luck in your search for a quality Kenwood hybrid at a reasonable price. Also check the For Sale listings in QRZ.com. I have a TS-530SP that I plan to keep for a long time.

I was trying to get you to exercise the X verter switch and Receive antenna switch on the rear panel and the RF attenuator button on the front panel. If that doesnt restore receive then would reach for RF sig gen and start injecting at SO-239 and work your way to the Ant terminal on the RF board or start at the Ant Terminal and work way back to SO-239.

You talked to the wrong guy or you are confused about what we are talking about ??

Dennis has been refurbing Wavetek 3002, 3001, and the 1170/U military units for a long time. I know several of our members who have bought one of his units. I bought mine from him. I believe Dick W0NTA also bought from him.

We are talking about replacing Craigs aging classic US military URM-25 RF sig gen with a Wavetek.

Dennis also from time to time has Wavetek Sweepers like the 2002A available. I have seen him advertise them on QRZ dot com and discussed calibration of my 2002A with him.

Bob / WA2JAJ

47779. 520se ALC

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-20 14:44:35 UTC
From: <jon_g4fut@...>
Topic: 47779 Message: 47779

First, I don't like this new layout of the forum. But more importantly, one of my hybrids, TS-520, has a problem with the ALC.
If I turn the mike gain to the point whereby I can be hear by other stations, Mike point 3, then then ALC bangs right over to right hand side. Turning the gain down and the ALC vanishes! So I have either massive swinging ALC or nothing at all. I wonder should I change the 2SC1515 (Q10) transistor as well as any resistor and capacitors there. Or does tha problem lie elsewhere? BTW, the rig puts our 100 watts .
Any advice will be most welcome please.

Jon

Are you saying the meter swings full scale hard against the peg or stop (FSD) and not just to the right hand end of the printed black ALC range box?

Does the S-meter function normally in receive mode? Reason I ask is the FET based meter circuit is shared and used as a voltmeter to monitor the AGC bus and the ALC bus and if the meter functions normally in receive mode as an S-meter then not a meter indication problem. Should see approx S9 with Marker on Drive control peaked.

You may be correct that Q10 is bad (leaky). Q10 is configured as a "dynamic zener" diode by tying the Base to the Emitter thru a 10k resistor. The Finals bias voltage is applied thru this 10k resistor to the control grids of the 6146 finals. When the RF drive envelope exceeds this dc bias offset on positive going peak the control grid becomes positive with respect to the cathode and current flows from the cathode to the control grid and back to the -C supply thru this 10k resistor. This current is varying at an audio rate when you speak in the mic. It is very low current on order of 40ua. This "modulation" current is rectified by Q10 and produces approx -1.0 vdc at the Collector. That negative voltage series bucks the + 3.2vdc RF-1 voltage which is your ALC bus or rail voltage. So the normal +3.2 vdc ALC bus voltage now becomes approx +2.0vdc. Your meter FET sees this 1.0vdc drop and drives the meter up scale. It appears that the ALC bus is dropping quite a bit more than 1.0vdc if indicator is banging against the stop.

You can measure or monitor the collector voltage and/or the ALC terminal post on the RF board with a 11 meg VTVM but it will pull it down maybe as much as a volt. I would still do that to see if it is dropping lower than to around 2.0vdc. I suspect it is.

If you replace Q10 suggest you check D9 or replace it while there as it is there to protect the base emitter junction of Q10.

Terry K9TW

Not often that Q10 goes bad and not much else in the circuit. If yo

Once again, you come to my aid Terry, and for than many thanks.
1. Yes, It goes FSD, especially when I switch on and I do get S9 when in calibration mode, and I have to turn the mike gain right down to notch 2 - 3 to get the meter into the ALC range. But then the audio is too weak to use for transmit.
2. The S meter operates fine on receive and corresponds with the readings of my other Kenwood hybrids.
3. In CW mode the ALC rerading corresponds with maximum power out and with Plate dip.
I'll try to get hold of 2SC1515 or 2SC 1515K (or equivalent) and replace the few components in that ALC circuitry.
Again many thanks
Jon G4FUT.

Jon Hate to replace transistor without testing to confirm it is bad, but very hard to do in circuit especially in this configuration. About best you can do is monitor ALC voltage on the ALC wire wrap post and it is going to confirm that it is dropping lower than approx 2.0vdc from 3.2vdc RF-1 level which you already know as evidenced by meter pegging high. Problem is absent a meter like a HP-410C (100 meg plus input Z) you wont know how much of the drop is due to your meter and now much due to the action of the transistor. I believe with an 11meg meter you should see something close to 2.0vdc with full scale ALC indication on a good rig. Any less than that would indicate to me that the transistor was producing more than approx -1.0vdc at its collector which it should not.

Good sub would be a NTE287. Just make sure you use high voltage transistor as you are dealing with the -C supply here to feed FG. I have purchased 2sc1515 and NTE-287 devices off of Ebay in the past.

OK we were not talking about buying sweep generators so that is what confused me when you responded that Dennis doesnt sell the sig gens I had recommended to Craig.

I was telling Craig to check with Dennis for a 3001/3002 series Wavetek RF signal generator before he would buy the Elecraft XG-3 DDS unit. For not much more money he would have a real full functioning PLL based RF sig gen.

Apparently you thought we were talking about sweep generators?

Did you get your Wavetek RF sig gen and if so is it OK? I forget who you bought from?

47787. New to the Forum - own a Kenwood TS-820

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-20 20:00:51 UTC
From: <sjkowak@...>
Topic: 47787 Message: 47787

Greetings fellow members,

Just a note to let you know I just joined your group and from what I have seen so far it has a wealth of information about the rigs we own.

I presently have a Amature Extra license that I earned last year. I have always been fascinated by ham radio even when I owned my first CB radio. Anyway, I own several radios to include the Galaxy DX 77 HML, Cobra 2010 GTL CB Base Station, Alinco DX 70 with the Alinco EDX-1 Tuner, and the RCI 2950.

I also own two Kinght Star Roamer Receivers along with a Hallicrafters model S-118 Reciever.

But my pride and joy is the Kenwood TS-820. Working that with the Alinco EDX-1 tuner and a 25" Marine SSB stick I have made quite a few contacts even though I only owned it for a few weeks.

Anyway moving on I would like to provide you with some info that would help keep your Kenwood rigs running a lot better. One of the biggest problems with these rigs is the contacts where the pin connectors are on the boards.

The Kenwood I just purchased was having issues with the meter, the digital display wasn't working at all and on some of the frequencies I couldn't get any TX power.

Well, I purchased a can of CRC QD Electronic Cleaner, removed all the plugs from the boards and squirted them down. I then took a Q-tip with a drop of oil on it and wiped it across all the pins. I did this to all the solid state board connections. Sprayed the potentiometers switches and anything else that I felt could have a corrosion problem.

Well, after doing all this the digital display came on, everything is working as it should and I have full power on all the bands. All my problems went away.

So If you are having problems with your rigs do this as a first step before looking towards replacing components. You'll be surprised as to how this rejuvinates the rig and puts it back into working order.

Oh BTW the QD Electronic cleaner is non-residual and dries almost immediately - when you spray your switches, work the switches back and forth to allow the cleaner to cover all the contact areas.

Regards

SteveKJR

Jon

I re-read your response and on No 1 it appears you are saying "ALC" goes full scale when you first turn the rig power switch on. If that is what you are saying it is not ALC you are looking at during powering on the rig. You are looking at the S-meter action. The meter is measuring the AGC bus at this time and not the ALC bus (rail as you would refer to it I believe). In receive mode none of the meter switch positions mean anything. Meter is always monitoring the AGC bus voltage in receive mode regardless of meter position. You can prove that to your self by turning on the Marker and peaking the meter indication and then put meter selector switch in any position and you will see it is functioning as an S-meter.

It is normal to see meter FSD on initial power on unless you keep antenna input grounded or on dummy load or turn AGC off, but grounding the antenna input is the best practice.

Only time you are looking at ALC indication is with the meter switch in the ALC position and the rig keyed or Send switch flipped to Send or mic PTT depressed. Now the panel meter is measuring the voltage on the ALC bus. Now to get ALC indication need Car Pot advanced in Tune or CW or to modulate the rig in SSB mode.

Just wanted to make sure you recognize difference between ALC and AGC. In Rx mode the meter is an S meter and none of the switch positions work. In Tx mode the meter serves whatever function you have selected with the meter select switch.

From: Wes Will
Topic: 47791 Message: 47791

Their "month" turn-around time was less than three weeks. They look perfect, of course. Bet they work as good as they look.

Now, the big question. What is the BEST method for getting to the crystals to de-solder the Chicken-Band ones, and replace them with the 10-meter original freq rocks? And the re-alignment will be done at the same time, so I'll be working on this for some time, starting tomorrow. I want to put in the meter and cathode protection mods as well, while I have the lid off. Any other protection or enhancements that anyone would recommend? These two I am going to consider MANDATORY for this and any subsequent Kenwood hybrids I manage to come across. (As if. I was lucky to manage to get THIS one, there won't be more. As much as I would LOVE an 830, I'm going to be happy with my little ol' 520SE, and leave it at that. Coveting would be considered hubris, knowing my karma, and the radio I do have will burn up at next power cycle if i get ungrateful.)

Maybe I should define the terms, considering that Karma business. "Best" right now should be defined in this case as the method LEAST likely to cause MORE problems.

I'd rather disassemble something a little further, or take off an extra piece, if doing it would give me better odds of success.

But from all I have learned so far, "Best" is probably exactly equal to "Least" when it comes to disassembly; the less I pull loose to get at these things, very likely the less risk there is of something else going kaput.

So, my 'best' route to the crystals, gents? Is there a document in the archives? (I'll look tomorrow, though the 'upgraded' web sire search system will probably give me bananas and clams instead of crystal replacement tips.

They're not, apparently, easy to get to in ANY case, so I am more than willing to take instruction here. I've had plenty and enough issues with this box already, so the recommended route, s'il vouz plait??

Merci Beaucoup Mes Amis!

Sounds like you have the shield ground hooked up to pin 1 instead of pin 4, and the hot hooked to pin 4.

When you do your wiring, do not refer to the numbers imbedded in the plastic on the back of the mic plug, as some from China are not correct. It's best to go by the manual picture on page 6 of your manual. The wiring is if you are looking down on the backside, pin side, of the connector.

Topic: 47789 Message: 47796

Alberto,

The E-V 638 does not have a PTT switch so I assume you have it mounted on a stand that has a PTT switch. Verify that your wiring is correct:

EV-638 Mic Hi = Kenwood Pin 1
EV-638 Mic Lo (shield) = Kenwood Pin 4

PTT = Kenwood Pin 2
PTT Ground = Kenwood Pin 3

Be careful that you have the plug oriented properly as it is easy to mix up the 1 and 4 pins (and the 2 and 3 pins).

Be sure your mic connections are securely soldered at the mic and the mic connector. Since touching the connector on the radio alters the hum that suggests a poor connection and/or RFI. Also, be sure that neither of the mic lines is touching any metal in stand.

Alberto,

Are you saying the hum is in your transmit signal? If so do you still hear the hum with the microphone disconnected and the SEND switch is used to key the transmitter in USB or LSB mode? If the hum disappears and the microphone wiring, as you said, is correct, check cap C3, .01ufd, between pins 3 and 4 on the microphone socket. Pin 3 is the PTT ground which should be connected to ground but the microphone element's ground lead is fed through C3, the .01ufd cap to ground on the microphone socket, pin 4.

Now I know a Drake T4XB transmitter is not a Kenwood hybrid but I experienced the same hum issue on sideband when I used a Tuner desk microphone. To eliminate the hum I inserted a .01ufd disc cap, just as Kenwood does on the microphone socket, in series with the microphone element's ground wire, problem solved.

I get quite a few request for the toggle buttons on the 520, 520S, 820 & 820S....
The buttons become loose due to the small keepers cracking & breaking...
Some think they have a bad switch...
Hard to find a take off toggle button that have good keeper tabs....
If you have a loose button then remove, put a small dab of JB-Weld Quick in the small socket, hold in place for a minute or so & Wahaa, just like new... :)

Dave,

The diodes in question, D1 thru D4, and D8 thru D11, are silicon diodes that can be replaced with 1N4007 diodes. They are simple silicon rectifier diodes.

You said you were replacing C19 and C20. Did you find those caps to be bad through troubleshooting?

Bob's got a solid fix if you're wanting to keep your own handles. If you want to get new replacements for these - either individual black or grey handles, or sets of five - check ebay for "kenwood paddle switches" and you will find these listed. Been selling them for more than a year and a half, many happy customers!

Best regards,

John - KF7QGU

John,

I wasn't an English major. I majored in EE. I did beat most of the English majors in an upper division American Literature course I took to meet an upper division general education requirement. The reason has not much to do with me. Its just that as an engineering student you learn early on to focus and how to study in order to survive.

I couldn't resist the temptation to make the comment. Currently the switches in my TS-520 are fine but I'm glad that you have them available in the event I, and others, need them.

I followed the directions(somewhat) on the WB4HFN site and removed the rf board. When I pulled out the shaft, the ground clip fell on top of the board. I told my self to make a mental note and get the tensioner later. Some point, i flipped the board over and lost the clip. How important is the clip, it is the one in the middle. I know it serves to ground the shaft. Is there an alternative to grounding the shaft?

Also, Im worried that the band wafers will not align correctly when I install the shaft. Is there a danger of that happening?

Thanks brian kb4mng

Brian,

I would not worry too much about the missing item. I would make absolutely sure however, that it is not wedged against, under, or otherwise touching another RF board component. If you feel the need you can us a piece of paperclip...or scrap off the lacquer on one of the YL/XLY's "bobby-pins," they're spring steel

As far as the chance of misalignment of the band switch wafers goes...you betcha...unless you
happened to take pictures or make a drawing or otherwise made marks to keep them "in-sync." I'll be happy to supply you a detailed explanation when you are ready.

Good morning Ms Mike.
Thank you,
The humming is only when I use the microphone (EV-638) only, when I use "send", audio is normal.
Also, I try a different microphone (generic hand mic), and when I use this, I don't have a problems.
I used the hand mic cable in the EV-638, to test whether the problem is in the original EV-638 cable, but still the problem.
However I have other question Sr, my EV-638 use a PTT pedestal, I see inside the PTT mechanism six different connectors, the PTT and Ground PTT are welded to two of them, what about the other connectors?

I'm a little frustrated with this, I find out about this microphone, and I always saw great reviews,though I recognize my poor experience with welding, this is the problem of modern radios, just connect to the power source, connect a antenna and ready to use je!.

Thank you again, have a excellent weekend.

Alberto,

It has been a long time since I worked with an EV-638. The last EV-638 I owned was in the late 70s, sold it when I sold my HW-101. I never cared for the flemsey PTT latch. The microphone itself is good but didn't like the PTT latch.

I have not been able to find the PTT switch wiring diagram. Maybe another member has an EV-638 desk microphone that has the PTT switch wiring.

If I remember correctly, the Microphone element connects to the PTT switch at the top of the PTT switch on the side of the microphone stand. The microphone element wiring does not have to go through the PTT switch, you can bypass the element wiring around the switch. You will have to keep the microphone element's shield ground separate from the PTT ground.

Alberto (and Mike),

I attached the schematic for the Heathkit HDP-21A mic that uses the E-V 638 head. Since the reflector will strip the attachment I copied it to both of your direct e-mail addresses.

According to the schematic, the original wiring has one side of the mic element grounded to the cable shield. Assuming you have the 3 wire shielded cable shown in the schematic you need to separate the black (PTT ground) wire from the shield. In the PTT switch you also need to remove the grounded side of the mic from terminal 2 of the PTT switch and connect it directly to the shield. The black wire must remain on PTT switch terminal 2 to provide a ground for PTT, the red wire on terminal 3. The clear wire, mic hi, can remain on PTT switch terminal 6. I assume that was done as a convenient tie point as no other part of that SPDT switch is shown to be connected to anything.

On the plug end of the cable you must separate the black wire (PTT ground) from the shield. The black wire connects to plug Pin 3, PTT ground. The shield connects to plug pin 4, mic lo. The clear wire, mic hi, connects to plug pin 1. The red wire, PTT, connects to plug pin 2.

I hope this helps you sort out the wiring and eliminate the hum.

Thank you Mr Ken.
I have closely followed all the instructions, I have tried to do the best job of welding, I also use another cable from a different microphone, but the problem remains.

I wonder if you can help me with the following: what about the connectors in the mechanism of PTT, now cable PTT and PTT ground use two of them, what happens to the other connectors?.

I'm trying to disassemble the portion of cable between the microphone and the PTT box, trying to find something wrong,
Thank you again for you valuable help.

Hi Ken,

The schematic attachment didn't make it.

If you would please, send the attachment to my private email so I can study the switch, it's been, as I said, a long time since I messed with an EV-638.

Your discussion is exactly what I said Alberto would have to do, separate the Microphone ground from the PTT ground. the normal PTT ground is connected directly to the KW chassis but the microphone ground is held above ground by a .01ufd disc cap. Alberto the only way you can eliminate the hum when using the EV-638 microphone is to separate the microphone element ground and connect it to pin 4 on the microphone socket. The PTT ground, a separate ground by itself, is connected directly to pin 3. That should eliminate the hum. The .01ufd disc cap connected between pins 3 and 4 on the microphone socket and the PTT ground and microphone element grounds are kept separate, allows the microphone ground to have an "AC" ground while at the same time keeping the microphone element ground above "DC ground". You have to separate the Microphone element ground AND the PTT ground into 2 separate wires. The microphone element ground is fed directly to pin 4, does NOT connect to the PTT ground. You will need 4 wire microphone cable to achieve this connection.

Topic: 47789 Message: 47816

Alberto,

The goal is to wire the microphone element so that one side is connected (soldered) directly to a wire that goes to pin 1 of the microphone plug and the other side of the microphone element is connected to the shield and then to pin 7 of the microphone plug. There should not be any switch in the mic line and neither side should connected to frame (PTT) ground. Two other wires are required for frame/PTT ground and PTT. No other wires are needed. The wire colors you use for any of the connections will depend on the particular cable chosen so it is difficult to reference color codes unless you provide details on the specific cable.

I have never owned the mic you have and do not have any personal experience with it so I can't help with the disassembly. If you have an ohm meter you can use it to verify your wiring. You want to ensure that neither side of the mic element is connected to ground or any other wire.

Keep the list posted on your progress or your findings and we will continue to assist.

Thank you very much for your help, I don't want bother with this topic a long time, excuse me.
Now your information give me more sense, however I am confuse with the terminal order in the PTT switch,
for this reason I am attaching a few pictures about how the PTT switch look in my mic.
The clear cable connect in a terminal PTT switch, with the mic cable (coming from the head mic)
The shield mic cable is the cable with a black tape around and bypass the PTT switch. (I need to join these cable and I use a piece of the internal part of a coaxial cable).
The red cable join in the PTT switch. (I dont know what connector number)
The black cable join in the PTT switch. (I dont know waht connector number)

Connector:
Clear Cable PIN 1
Red Cable PIN 2
Black Cable (PTT Ground) PIN 3
Shield (MIC Ground) PIN 4

Thanks again.

Alberto (and Mike),

I attached the schematic for the Heathkit HDP-21A mic that uses the E-V 638 head. Since the reflector will strip the attachment I copied it to both of your direct e-mail addresses.

According to the schematic, the original wiring has one side of the mic element grounded to the cable shield. Assuming you have the 3 wire shielded cable shown in the schematic you need to separate the black (PTT ground) wire from the shield. In the PTT switch you also need to remove the grounded side of the mic from terminal 2 of the PTT switch and connect it directly to the shield. The black wire must remain on PTT switch terminal 2 to provide a ground for PTT, the red wire on terminal 3. The clear wire, mic hi, can remain on PTT switch terminal 6. I assume that was done as a convenient tie point as no other part of that SPDT switch is shown to be connected to anything.

On the plug end of the cable you must separate the black wire (PTT ground) from the shield. The black wire connects to plug Pin 3, PTT ground. The shield connects to plug pin 4, mic lo. The clear wire, mic hi, connects to plug pin 1. The red wire, PTT, connects to plug pin 2.

I hope this helps you sort out the wiring and eliminate the hum.

47818. Introduction and a question

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-22 18:09:58 UTC
From: Joe Reed
Topic: 47818 Message: 47818

Allow me to introduce myself, my name is Joe N9JR and I recently acquired a new to me TS-530S. Not my first hybrid, back in the late 70s I had a 520S that I used to run mobile in a Ford Fiesta. Needless to say back in the day if you rode with me you rode in the back seat.

And ~20 years ago I had a 530S, but sold it. Over the years I missed the genre, but DXing took priority. Recently the yearning for a radio of the era led me to pick up this 530S. It has the narrow SSB and CW filters, seems to be solid electrically, and is awesome looking. Lucky me!

After buying it I was researching parts, options and so on. It is almost 33 years old, and some sites on the Internet say replace the electrolytics. I know there is also a school of thought that says if it isn't broken don't fix it. After lurking on this group for a month I realize there is a tremendous body of knowledge and I'd like to avail myself of the collective expertise. Should I replace them all, just the HV caps or just use it.

Thanks in advance,
Joe N9JR

Welcome aboard Joe,

Running mobile 520 on a Ford Fiesta??? Never thought the electrical system had that much power! hihi

As you have figured, there are different schools of thought regarding replacement of electrolytics in these "older" rigs. I'll open a big can of worms on an already heavily discussed
subject...but...I would replace the HV caps. Failure of one or, both...will make life very bad
for you and the rig. The HV cap replacement kits..are available through numerous sources: hybridrestore.com, Ken Kemski-k4eaa(google him), and several EBAY sources, or order yourself from your choice of electronic parts providers.

Good luck and welcome aboard. Thank you for properly identifying yourself.

Terry:

It has taken me a while - press of work among other things, but I have gotten back to the deaf 520S. I have injected a 1 microvolt signal and a 50 microvolt signal at RFG, and I can hear very little difference in volume, and the S-meter does not deflect with either signal. I have a good ANT Coil board from Bob Mansker, but before I .tore the radio apart to install it, I wanted to make sure that L1 is the problem.

I replaced Q3 (3SK35 (GR) FET) with an NTE454 (N-Channel dual gate MOSFET) and receive came back to life. I suppose what I blew was Q3, and as soon as I can get the proper semiconductor, either a 3SK35(GR) or the NTE replacement, an NTE222, I will put that in.

Now, what is the difference between the NTE222 and the NTE545, if any, and should I replace the 454 with the 222, or should I just leave well enough alone?

John:

Well that was whole purpose of injecting at RFG. If rig had come alive would have told you Q3 RF amp was good and L1 was the likely culprit. When that didnt occur then next step would be to measure Q3 D-S-G1-G2 dc voltages.

You can use either the NTE454 or NTE222. The NTE454 is a high frequency device. It has about same gain and about the same input and output capacitance but a lower noise figure. It is however much more expensive and not required for this application unless only thing you can find.

Also can use a 40673 or 3N211. I have bought and used the NOS 40673 devices from Scotts Electronic Parts who sells parts for crystal radios and has some NOS mosfets at good prices.

Thank you for your help, terry. Between this little exercise, and reading the travails and tribulations of others asking for your help, I have gotten a better working knowledge of the radio. Following your instructions, and studying the block diagrams is a great help in understanding the circuit performance. I appreciate your patient help and guidance, both for me and for the others, for I have learned a lot following what they have done, and what results they achieved.

John:

It would have been nice if Kenwood would have put a little more meat on the bones as far as circuit descriptions go in their documentation, but it is what it is and better than many mfgs. Heathkit was among the best years ago. Studying what KW does provide along with the block diagram and schematics will serve you well with time.

Just keep up your thirst for knowledge and use these kind of operational problems as a way to learn. Nothing wrong with asking here, but in parallel with that I most appreciate helping those willing to expend some energy and help themselves by cracking the manuals. Easy to just give the answer, but very little learning occurs.

Have fun.

Joe,

Thanks for the reply. Good to know the little wire will not make much difference. I really like to keep things original when I can.

I have wb4hfn article on the wafer fix. I have removed 3 so far and it has gone well. Just hope it all goes back together ok!!
Should I remove the switch at the end of the shaft in the final cage?

I hope to have it aligned properly. The article states the indention on the plastic center must go to the 9 position. I also made sure it was on 10 mhz when I removed the shaft.

Brian,

Why would you want to remove the switch? Is it somehow malfunctioning or otherwise broken? If none of the above, there's no reason. It's more work than you would care to get into. The contacts can be cleaned in-place. Just use a good quality cleaner/lube and blow off with canned air...aka "air duster." I can not stress enough about making sure that the band switch wafers..etc are properly aligned. Now may also be a good time to replace the band switch shaft coupler...if not done already.

47827. Checked archives, no help. Explicit instructions please, disassemble to replace crystals?

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-23 07:31:23 UTC
From: Wes Will
Topic: 47807 Message: 47827

The yahooligan-run web site has no information in it that I can find about proper disassembly procedures for the bandswitch. Other posts have touched often on the "keep everything so you get it all back lined up correctly" and I think I have that covered with a marker and LOTS of pictures.

But the precise steps needed to safely remove the band switch shaft, JUST ENOUGH to get to the sub-board which has the HET/OSC crystals on it are nowhere to be found. I've checked the archives of messages as best the stupid yahooligan web site will allow. It comes up with a lot of GARBAGE, most of which has NONE of the search terms on it.

I have most of a years'-worth of messages in MY OWN archive, and searching those gets me those line-up warnings. (Didn't really need those, since that is beyond "obvious. I have more than three functioning neurons, thanks.)

I will go it by guess and by golly, using what appears to be the least damaging way to get this thing apart, if nobody can point me to better instructions.

It has been done at least once by someone who apparently DOESN'T have more than three functioning brain cells, when they put these stupid chicken-band crystals in here in the first place. If they can do it, I can as well, I am certain.

But I'm also savvy enough not to do it the hard way (without advice) if I can help it. This is me, asking for that advice. Any pointers here would be appreciated.

I will be applying the mods to protect the finals (grid current loss) and the meter (over-voltage) while I have it open, too. Any others recommended? Anything that will make this thing more bullet-proof?

I'm interested in getting this repair done, ONCE, then realigning everything and NEVER opening the box again if I can manage to avoid it. Spent too much time with the covers off as it is.

Joe,

I would do the HV caps including oon the IF board and for me I'd replace the relay at the same time. Have a look in the final unit to see if the small green choke and RF cap needs replacing. The cap usually cracks from heat from the valve.. Make sure you give the PA a good blast of air and remove any dust build up, give the fan a small amount of lube whislt your there. Remeber to discharge the HV before sticking your fingers in the radio.

These are the minimum things that I change when refurbishing the 530 or 830s Ken, K4EAA has all the parts you would need, he has real fast deliver too.

Regards,

Dave

Tim,

There is no overt reason to remove the diodes to enable the WARC bands. You can very simply cut one wire. Take a look at Pg 28 Section 6.5 of the 830S instruction manual. It describes a very simple procedure to enable the WARC bands. I recommend it..vs cutting the diodes. Make sure that you leave a bit of length on either end of your cut. Put some electrical
tape on either end..and tuck it away. Also, after cutting the wire in question...I suggest that you do a "basic" RF deck alignment...as stated in the manual.

Brian,

Both are friction fit. The clear plastic "pointer" has two tangs that fit into slots of the shaft. With GENTLE force you can use a couple of soft tools..or if you're lucky..some longish fingernails...on either side and rock and pull towards you...GENTLY! Remember...that this part
has probably been there for 20+ years without being removed! You may also use some very light oil...to help remove the part.

I must have mised the purpose of the list, so please forgive my questions! What are you gathering the sn for and is this for the original purchase only, or is this a project to see what rigs are still in operation and by who as a result the rig could be tracked through years of hands if it traveled.

ok so now that I may have just confused myself, maybe someone can answer the questions!

Mr. C. Robinson,

It has always been a question when certain models of the KW hybrids were manufactured/sold or, otherwise put in service, Many of us, myself included purchased used rigs. Mine was an TS820S from an SK back in circa 1982-83 The original purchase document..has now been lost to history...so when was it manufactured? Kenwood has not been overtly helpful in tracking or
documenting when a model comes out and with what beginning serial number...we can make assumptions.

Tim,

The connector that has the wire that needs to be cut is best accessed from the underside of the rig. It is a small BLUE wire on CONNECTOR #6 PIN #4 of the AF board. Make sure rig is OFF and UNPLUGGED, as you'll be working within 2 inches of 900+ volts DC...which will really
complicate your problem. You can either let rig sit for an hour or so, or using a multimeter capable of measuring DC volts, check for High Voltage on the terminals of the "round thingies"
clearly visible on the underside of the rig. If you are not comfortable with this, find someone who is. I do not know your level of experience. Connector #6 on the AF board is just towards the front of the rig from RL-1(relay -1) on edge of the board. It has 5 wires...can not remember all the colors off the top of my head...but cut the small blue one....I think... third from the right. May I suggest that you obtain a good clear copy of the "Service Manual." It has X-ray views of the boards and is a great help.

I apologize for the usage of "RF deck alignment," being unclear. What you should do, starts on Pg 27, Section 6.3. Even though the rig will receive on the WARC bands it will not transmit until after the wire is cut.Go through the basic "receiver adjustments," then proceed through
the transmitter adjustments. I have found that the adjustments for the WARC bands as the rig comes from the factory..are a bit less that good

I'm doing up a data base and once we get enough
serial numbers from all the different models,
I'll post it on my Kenwood site. Once that
happens a person should be able to tell aprox.
when his radio was built by comparing DB numbers.

Tim,

If you do go about cutting the blue wire, just be very careful not to apply any pressure to the counter board. I have had 2 that have been cracked in 3 places, easy to repair, but if a little care is taken then no problems

Subject: Re: [TS-520_820_530_830] WARC bands

Tim,

There is no overt reason to remove the diodes to enable the WARC bands. You can very simply cut one wire. Take a look at Pg 28 Section 6.5 of the 830S instruction manual. It describes a very simple procedure to enable the WARC bands. I recommend it..vs cutting the diodes. Make sure that you leave a bit of length on either end of your cut. Put some electrical
tape on either end..and tuck it away. Also, after cutting the wire in question...I suggest that you do a "basic" RF deck alignment...as stated in the manual.

47847. TS 530 Band Switch Disassembly

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-24 13:31:41 UTC
From: <bsa0791@...>
Topic: 47847 Message: 47847

I successfully removed the wafers and cleaned the contacts and soldered the rivets.

The 530 was owned by a smoker and the inside is very nasty. I'm in the process of cleaning it up.

Is there a trick to make sure the band switch wafer is 90 degrees to the main board? It would be very easy to slightly have it off 90 degrees when you go to solder it.

Thank you brian kb4mng

47848. Replacement Kenwood Hybrid sprockets are EXCELLENT

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-24 14:08:13 UTC
From: Craig Roberts
Topic: 47644 Message: 47848

The Kenwood Hybrid replacement sprockets offered by Gregory, NR6C, are excellent! Two sets of the upper sprocket wheels arrived at my QTH Saturday and, by that evening, one set each had been installed in my TS-530S and TS-830S.

As Terry noted in his prototype review a couple of weeks ago, these 3D printer-manufactured replacement parts are easy to install, requiring only the removal of your radio's top cover for access to the DRIVE control shaft with its chains and pulleys. No boards need be pulled, no connectors undone nor wires desoldered. Just loosen the four shaft coupler screws and the set screws on the sprocket wheels andf you're ready for the removal and replacement operation. Kenwood even provided a step on the three phenolic shaft mount uprights to make things easier upon reassembly. You'll see what I mean when you get into this simple project.

Installing the first set took me about 45 minutes. Most of that time was spent aligning the new upper sprocket wheels with the lower ones mounted on the three variable caps. (VC1, 2 & 3). Perfect alignment is the key to absolutely smooth operation of the DRIVE control. Utilizing a simple trick, the second set of of new sprocket wheels took less than half the time to install. The "trick" is to mark the position of the old sprocket wheels on the Drive control shaft before removing them. I used a "Sharpie" marker for the job, but one could score the shaft lightly along the edges of the original sprocket wheels for a more precise reference. I took pains to replicate the original factory installation regarding the positions of the chain tensioners and set screws, too. This esthetic step is not really necessary, but makes for a more satisfying repair for an anal someone like me who considers the appearance of the inside of a radio as important as its external cosmetics.

Does my radio now perform better, one may ask? Well -- to be honest -- no. The cement and cable tie repair of the old, cracked sprocket wheels as suggested by my friend (and yours) Mark, WB0IQK, worked perfectly well to keep the old, age-damaged sprockets from slipping and putting VC1, 2 & 3 out of sync. But, I must say, the shiny replacements from Gregory certainly look terrific and give one the sense of permanency that only new parts can impart.

Thank you Mark for your excellent repair instructions and thank you Gregory for these beautifully executed new components. As Mark suggested yesterday during a pleasant QSO, we should brainstorm a bit about other parts that could be fabricated by the nifty 3D printing process.

Oh, and thank you Terry for being our enthusiastic promoter, beta tester and initial reviewer.

73,

Craig

Dayton Hamvention Kenwood Legacy Forum:
This year will be the first year for the Kenwood
Hybrid Legacy Forum to be held at the Dayton
Hamvention. The forum will be Sunday May 18,
room #2, 10:30 □ 11:30. The following preliminary agenda has been proposed:

```
* History of the legacy products.
* Resource help with parts, documentation, etc..
* SDR integration into the legacy line.
* Rewinding a TS-830 L41 coil.
* Tips & Hints.
* Questions and Answer Technical Session

We hope to see you there.

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm
```

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

```
The Saturday 40 meter net had 18 stations
checking in under good band conditions. There
were no new stations checking in. We had the
following number of radios checking in.

4 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
4 running TS-830S

I was running my TS-940s with an L4B amplifier.

The Sunday 20 meter net we had 30 check-in under
good band conditions. We had the following number of radios.

6 running TS-520(x)
0 running TS-530(x)
3 running TS-820(x)
```

5 running TS-830S

I was running my TS-820s twins, the TS-820s & R820.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Brian-
I have done several TS-530/830 RF decks now, as you describe, by carefully de-soldering the 7 switch wafers, examining PC board traces to minimize damage during de-soldering, cleaning them in Tarn-X silver cleaner, then polishing the copper surfaces of PC traces and mating switch contacts, then soldering them together.
After all 7 wafers are done I follow this procedure:
1. I test each switch wafer with an ohmmeter for continuity in each position. While doing this I give the switch wafer a final visual inspection.
2. I insert (very carefully) all of them back into their correct location holes on the board. I visually check the PC pads to make sure none are damaged or pushed upward from board and damaged. The wafers normally stay in place by friction-fit.
3. I double-check that the wafers are in their correct locations.
4. I double check that the wafers are in their correct locations one more time.
5. I install all of the spacers and two long screws, but only hand tighten loosely. Make sure have spacers in correct positions - they can be tricky!
6. I insure the rotary switch center -sections of the wafers are all turned to their "indexing" positions (small notch at 12 o'clock, if I recall correctly)
7. I slide the bandswitch rod through all of the wafers. I test that it will turn freely, examine for any issues, etc.
8. I examine the assembly to insure all wafers are down against the board and at a right angle, and that spacers are installed correctly.
9. Now I solder the pins on each wafer to the PC board traces as found from factory. During the soldering I double check that the assembly remains all the way down against the board and that there are no damaged traces. Sometimes a pad will be lifted/damaged and you must install a tiny wire to insure good continuity to PC trace.
10. After soldering I do a final inspection, then remove the bandswitch rod, install the RF board back into radio.

In my opinion the best way for someone who does not do this very often is to do one deck/wafer at a time. No way to mix up the decks and can look at others to see the indexing as the non-removed ones should all remain in alignment after the bandswitch shaft is pulled.

Cannot assemble all the decks and re-insert back on the RF board as the 2 RF shields remain on the board. Unless you unsolder them and I would not do that. They are held by 4 heavy tabs with a twist to secure them to board.

Very easy to re-align. There is a nice round white circle indented on the white plastic rotor and if you rotate that to 9:00 position you are good. There is also a small U shaped notch that you could rotate to approx 4:00 but I think aligning all wafers at 9:00 is simple and easiest to see.

If you literally follow W0NTA procedure and place band switch to 10 mhz position all the white circles will be aligned at 9:00.

One thing you have to be very careful is 'unsoldering the folded over pins (2 per wafer/deck) as it is easy to lift a pad (even using the Hakko) and I dont want any jumper wires installed on my rigs or my customers if I can prevent it. When re-installing no reason to bend over any contact pins. If you have lifted a pad at one of these folded over pins you might be able to fold it toward the side that has some remaining pad to resolder it.

Subject: [TS-520_820_530_830] TS 530 Band Switch Disassembly

I successfully removed the wafers and cleaned the contacts and soldered the rivets.

The 530 was owned by a smoker and the inside is very nasty. I'm in the process of cleaning it up.

Is there a trick to make sure the band switch wafer is 90 degrees to the main board? It would be very easy to slightly have it off 90 degrees when you go to solder it.

Thank you brian kb4mng

Hi Mark,

I sold my TS-520SE a couple of years ago and upgraded to a TS830S, however I still
have data on the TS-520SE:

SN: 0100270
Date of Sale: 12 Aug 1980
Dealer: Modry Electronics
Box 506

Hi Mark,

The Audio Technica microphone is used yesterday was the ATR1500. For our use, it sounds just a nice as Bob Heil's PR series at about half the price. It's essentially a clone of Shure's nail-driving SM58. Back in my AM days a few years ago, the very best audio I ever heard was from a guy using an SM58. The rest of us, some with multi-thousand dollar studio condenser instruments hand crafted by elves in Germany, felt very badly.

Here's the scoop on the Audio Technica clone:

http://www.audio-technica.com/cms/wired_mics/2a964c199518adc1/index.html

Oh, here are the serial number of my two existing Kenwood hybrids. I'm sorry I don't have the dates of sale.

TS-830S No. 1030342 (unknown date of original sale)

TS-530S No. 2021470 (unknown date of original sale)

Talk with you soon.

73,

Craig

I see the freq. response is 60-15,000hz. Might be
best to run this through an equalizer and trim
off some of the lows. The best might be to cut
them off at around 300hz. Do you have one in line?

The local AM group did some testing several
months back on some other mics as guys were
getting their equalizers set up and that's about
what we came up with. We also cut them off about
4,000hz. So 300-4,000hz seems to sound the best on AM. This was on 6 meters.

I, personally, would not buy a Rigol. I've seen a number of failures on only 2 and 3 year old models.

I would recommend an old(ish) analog Tektronix. A Tek 465 is 100MHz, but is heavier than a Rigol. A 475 is 200 or 250MHz, but otherwise very similar to the 465. Both of these can be had with an optional multi-meter mounted on top. A slightly newer model such as the 2245 will still be 100MHz, but is much lighter. For just a little more money, you could get a 2247A, which has a very handy built in counter/timer. It can do frequency measurements, period time, cursors, cycle counter, automatic phase measurements, and much, much more. I've had mine almost a year and I'm still finding new features. The 2252 is very similar, with the addition of GPIB control. With the proper adapters it can be interfaced with a computer. This family is also known for very good reliability. The trade-off here is that the newer model you get, the harder it will be to repair it, should a failure occur. With enough patience, all of these can be had on Ebay for under $300.

If I were you, I would get the 2247A or 2252.

Dave Jones from EEVBlog Did a good episode on buying a your first scope:

I have the 100mhz Rigol 1102E. I finally replaced my Tek475B that was getting tired. I started like most with 10mhz and 20mhz scopes and eventually ended up with a Tek465B for quite a few years and then the 475B for last 5 years or so. Never owned any of the later 24xx or 26xx models.

Phil Salas did a nice review in QST on the Rigol and comparable Tek digital scopes. If you are ARRL member can find it on line.

If you have never had a digital scope it will take some getting use to the display as it has a different look than an analog display. I am still learning how to use mine. Very nice to have all measured parameters displayed on the screen.

You dont need 50mhz bandwidth to neutralize. Can use a 10mhz or 20mhz. The display may begin to flicker and loose sync and blank as you get close to the null so wont be as accurate as using an RF millivolt meter or RF probe but good enough.

However, for accurate measurements while troubleshooting and aligning KW hybrids I wouldnt get anything less than 100 mhz BW scope. Rough rule of thumb is you need 5X times frequency you want to measure. A 100 mhz scope will read approx 3% low at 50 mhz. Remember the BW rating is the point where the measured amplitude of the signal has decreased by -3dB or 70.7%!

So a 100mhz BW scope will allow you to measure at approx 3% accuracy up to approx 30mhz. Good enough for most KW hybrid measurements. Only thing higher in frequency will be VCO on 10 meters.

I use an older TEK TDS380 digital scope and the biggest issue I find is that of aliasing. You have what you think is a nice triggered waveform at one sweep rate, only to find that the scope is aliasing and the actual waveform is at a much higher frequency.

When I am probing unknown frequency waveforms, I usually run the sweep rate up to the fastest speed, and then work backwards until I get a good triggered lock. When I made the switch from analog to digital back 15-20 years ago, it took a while to get use to this 'feature', but now I don't even notice.

Another resource I would recommend you read is a series of articles explaining the advantages of analog scopes over digital. He refers a lot to "plug ins" which were used in the higher-end lab grade scopes, such as the Tektronix 500 series and Tektronix 7000 series.

http://readingjimwilliams.blogspot.com/2012/02/vintage-scopes-are-better-part-1.html
http://readingjimwilliams.blogspot.com/2012/02/vintage-scopes-are-better-part-2.html

Use any analogue 'scope with greater than audio bandwidth. You won't need 50MHz. Even a 10MHz 'scope will be more than adequate.

Pick up any old dual-trace analogue 'scope that you can buy locally and see working.

Sid

If I had to buy just one instrument to troubleshoot and align KW hybrids it would be a RF millivolt meter. Almost no learning curve and much easier and faster to use than an O-scope. I favor Boontons and use a 92E analog. I prefer analog for peaking and nulling operations. A Boonton or Millivac is a good choice. Of course must have the probe and a 40dB or 100:1 capacitive voltage divider is required to extend range from 3 volts to 300 volts.

With this instrument you can quickly measure and adjust Het Osc levels, Carrier osc level, VCO levels, VFO levels, Carrier null and balance, Neutralizing, and run TX level diagrams to measure and trouble shoot RF drive from the TIF amp to the dummy load.

Mini-Circuits Labs makes a USB model PWR-6GHS that you use with your laptop. Not cheap ($800.00) but if thinking about a new scope then might want to look at it.

Your cheapest option is a Heath VTVM like an IM-18 and two germanium diode probes. Need a single diode like a 309C and a 3 diode like a PK-3. Only limitation here is you will not be able to measure the TIF level as too low for this method. To measure 8.830mhz TIF level a Tek465B will work fine

With a RF millivolt meter, frequency counter, and good RF signal generator you can do about 99% of every thing you need to do on a KW hybrid.

Sid: As you can see your question has resulted in as many opinions as people. The challenge for you is to sort out the good from the not so good and the just flat wrong.

I disagree with Gordons counsel to use "any scope with greater than audio BW". I would be doing my customers a real dis-service to charge them for a complete service manual alignment trying to use a old 5mhz or 10mhz BW scope. That would be pretending and playing at KW hybrid service if not fraud. What kind of scope do you think Jim Showker, Ken Kempski, Cliff Avvid, DIck Housden uses to service KW hybrids? These guys dont charge several hundred dollars and skip steps in the alignment due to test gear limitations.

Your question was: What scope do you recommend to allow me to neutralize and SERVICE my TS-830. It has already been stated correctly that you do not need a 100mhz BW scope to neutralize. However my advice still stands if you are going to buy a scope to service your TS-830 you need nothing less than a 100mhz BW scope. Tek465 and 475 models abound on Ebay and parts units can be purchased to address such things as worn out vertical attenuators and worn out sweep controls, etc. which most of these have due to aging.

Most of us start out with modest test gear. Some even homebrew their own. It allows several things. 1. Learn how to make measurements. 2 Learn how to use the particular piece of test gear 3. Most importantly learn the limitations of that test gear and sources of measurement errors. 4. Develop work arounds to overcome some of those limitations. For example a general coverage receiver can serve as a piece of test gear. You can do reasonable close neutralization by listening to the null on another receiver.

As to Gordons counsel I ask when is last time he has had low RF drive problem rig on the bench and tried to accurately measure the output of the TIF amp from the IF board with an O-scope that had just greater than audio bandwidth?

I would sure hate to send my KW hybrids off to any of the reputable service shops and pay $250 to $300 for alignment only to find they used a 5 mhz Dumont scope!

My counsel still stands relative to question you asked about your TS-830. Dont need 100mhz scope to neutralize, but I would buy nothing less for service and alignment work if you are serious about it and want to approach factory spec performance. It just depends on what your end goal is and your definition of quality. Also think about a RF Millivolt meter in lieu of the scope. Can always add a scope later.

As to Digital vs Analog scopes will leave that up to you. I believe the "aliasing" problem is really due to unfamiliarity and operator error and with experience you should be able to measure your TS-830 8.830mhz signal by starting at the highest time scale and then stepping down the horizontal sweep until you have a clean stable display. I had to learn this pretty early when I transitioned to my Rigol 1102. I am no digital scope expert by any means but have no problem using it to make required rf signal measurements on any of the KW hybrids.

I would really be good for Sid and other newer hybrid owners to hear from the fellows who repair and service their own KW hybrids and started out very modestly and have upgraded their scopes or upgraded from rf probe/vtvm to rf millivolt meter in last year or two and

why they did that.

The OP was talking about setting the neutralising. You don't need anything particularly special to do that, but having a 'scope makes it easier.

A dummy load and a reasonably sensitive 10m receiver will work just as well.

The Heathkit Cantenna has a RF tap on it that serves as an RF probe on the output of the antenna. You connect it to a VTVM.

The only test instrument I have is a FET analog VOM. I have heard from K4EEA that I could use it to neutralize it with a "modified RF probe (all you need is the diode). I am looking around for a good scope , so Gents, thank all of you for your replies.

FET VOM will be fine. Similar to using VTVM for this task. Just becareful with a single diode RF probe. Easy to burn out the diode.

If going to use the FET meter and RF probe I would make a 50 ohm dummy load from two 100 ohm 1/2 watt resistors in parallel soldered to a PL-259. Leave the resistor leads long so you can connect your RF probe across them to measure the RF voltage drop.

After loading rig to full output power into a normal dummy load then flip Screen grid switch off and remove the high power dummy load and connect your miniature dummy load to the rig. Connect your Rf probe across this load and connect its output to your FET VOM.

Yes you could just use a signal diode and place it in series with your VOM test leads to use it as an RF detector. Place it in hot or Red lead and connect Black lead to rig chassis ground. You are not interested in measuring the RF voltage just being able to null it. You dont care about diode polarity.

Make sure you use an insulated tool to turn the neutralizing cap to avoid shock hazard. Also you will be within reaching and touching distance of the 900vdc anode voltage working in bottom side of the chassis.

You may want to exercise NC cap first with rig line cord unplugged. It will turn stiff by design.

If you have talked to Ken about this I assume you would have likewise asked him about a scope? I think could have saved a few keystrokes.

Sid,

While a 50Mhz scope would be nice to have, you don't need a 50Mhz scope to neutralize the finals. A lower frequency scope will work. I use a 20Mhz scope and I achieve the same results a VTVM with an RF probe does.

As you discuss the different 'scopes...what about the one that ARRL lists at http://www.arrl.org/shop/Parallax-USB-Oscilloscope?

Would it be useful for the work being contemplated? Not knowing anything about scopes, I've been following this discussion with interest...but have wondered if the $140 buck price tag would be worth it or not and not been willing to pull the trigger and then find out it wasn't really useful. Got the computer...just not sure if this would be useful or not.

I'm frankly not so sure about USB Oscilloscopes.
I tried an Australian Bitscope model when I bought my new GW-Instek 1102. The Aussie one claimed some quite remarkable bandwidth figures but was VERY hard to drive. The GW has a genuine 120MHZ (Measured) bandwidth using one channel and can do anything you need to service Ham gear. Also it was only about $640 NZ (about $550 US). The Bitscope went back to Aussie!

However there are quite a few good digital scopes on the market in that price range, just remember that they can have aliasing problems if not set to the correct sweep rate.
I would NOT be without a scope and these days you need at least 100 MHz bandwidth to service modern HF gear properly.

WARNING!!! David. That little scope is NOT compatible with Windows 7 or 8.
(according to its own Ad). That means that you would have to use it with
an older laptop
, which also means that the performance would not be that great.
My experience is that USB scopes are VERY software dependent and many of
them have much slower
A/D converters in them that only work at high frequencies with
repetitive signals.
In other words they have to see the same signal many times to display it.
It looks quite like the Bitscope and I also found that it was very hard
to use as test equipment, simply
because it was so small and light.

Hi Group,
I have been using a PICO Scope 2204 with the built in tracking generator for about 2 years now and have found the software quite easy to operate.
I use it mainly to characterize filters but as a scope it does a good job, no issues with aliasing either. If you're in a hurry (?) just hit the auto configure button and viola ! Good readings every time.
I also have a trusty old CRT scope as well because there are some things that I feel that it does a bit better (it's probably only me though, I do prefer Analogue.)

Use an antenna switch . Feed your TS as directed into a dummy load through one position of the switch. Hook up a receiver tuned to 10 meters to another switch position (no antenna) and neutralize away. The switch's internal leakage provides just the right signal level.

47880. TS 530 Band Switch

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-26 01:37:28 UTC
From: <bsa0791@...>
Topic: 47880 Message: 47880

I did the band switch fix and everything seemed to go together fine. I disassembled the switch per the instructions on the web and it did not seem too hard. Very time consuming because I really took time to make sure it was right. This afternoon, I reassembled the TS530 and left the cover off. I made sure the heater was off and powered the rig on. Immediately, there was blue arc from the rear wafer, closest to the cage. I quickly cut it off. I pulled the rf board back out expecting to see the switch vaporized. Every thing looks fine. I checked with an ohm meter to make sure that the contacts on the wafer was not touching the two support bars holding the assembly together. What I did find, was a white mark on the rear metal spacer that rest on the wafer. It appears there was arcing going on between the wafer terminal and the little metal support but there is no direct contact but the two seem really close together. Any idea what is going on? I'm sure the radio is more than likely toast!

Brian,

I had a similar experience awhile ago. I used "conductive ink" to do the band switch repair. I had just a bit too much...and it was touching the end small ferrule that goes over the long screw. Saw a nice blue spark...and a zap. Did not hurt anything...except my pride. Take a VERY close
look at the spacer(s) and make SURE they are not touching any part of the wafers foil traces

Exactly. My broader point is that there's just about nothing in these radios where you need an accurate measurement of RF voltage - just an idea of "less" or "more". If you're getting into the things where you need a really good measurement of RF voltage, there are a whole bunch of other expensive specialised things you need too.

I still stand my my point that for the vast majority of repairs of equipment, someone with no 'scope at all does not need to be going out and buying the latests and greatest 500MSPS digital storage wunderkind. When these radios were new you *wished* you had a 5MHz 'scope...

For that sort of money you could pick up a nice old second-hand HP DSO, which will not be as portable as something you stuff into the side of your laptop but will actually work.

Furthermore, many of these USB 'scopes seem to only support Windows XP, so you need to be some kind of autistic savant to get through all the training courses to learn how to use Windows *then* figure out the 'scope.

Against my better judgement I will respond to this. I dont know if you fellows are just not that savy or you are suffering from that very common ham malaise of bring frugal or just plain cheap?

I disagree. The Cantenna does not serve as a very good "RF probe".

First of all it is a fixed 100:1 voltage divider so not very useful for measuring low levels of RF.

It is relative power indicator and I would never use it to try to measure and set things like VFO output or Carrier Osc output levels in a KW hybrid or any rig. Could use it for some peaking and nulling operations realizing the null level is directly related to the voltage divider ratio, but certainly not for measurement.

Lastly, its dc output is very frequency dependent.

For example at 100 watts into the Cantenna on 7.2 mhz the detector will produce approx 2.25 vdc, at 14.2 mhz it will produce approx 1.35 vdc, and at 28 mhz it will produce approx 4.5vdc. Each Cantenna is a little different in this regard so have to run your own spread sheet.

I suppose this falls into the "more or less" quality standard of rf voltage measurement that is being espoused here? Sure glad factory didnt use that approach.

We all have definitions of quality and good enough. For the newer folks following this banter suggest you look at the service manual and see what Required Test Equipment is listed and look at the specs of that gear. You will see an RF millivolt meter listed capable of measuring 10mv at greater than 50mhz. There is a reason the factory used this level of test gear and you should be glad they did.

Also look at the acceptance criteria listed for RF voltages and you will see most are +/- 1dB. For the Carrier Osc level of 300 mv that means 267mv to 377mv. If you dont know how to figure this tolerance write me off list and I will help you.

Does this mean you cant use your Heath VTVM and 309C probe? No but it does mean it has limitations that wont allow you to measure and adjust all the key signals. For example to measure a 15mv TIF signal. You will see no deflection on your VTVM. It also means that a Carrier Osc that has been set to precisely 300 mv with a 100mhz O-scope or a Boonton 92E Millivolt meter will read approx 200mv with your Heath test gear. There is a reason for setting all the Mixer LO levels where KW wants them.

I am moving on and you guys can repair and maintain your rigs at any performance level you chose. If any of the new folks need help I will be glad to try to assist you off list.

Terry K9TW

47887. RE: TS-820 frequency jumping

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-26 17:14:46 UTC
From: <dougc314@...>
Topic: 47316 Message: 47887

Based on the report, I assume.

1) The RX and TX frequency of the radio is moving. (for at least several seconds at a time (can hear it)
2) Its staying phase locked.
If it wasn't staying locked then it would almost certainly move way more than a few kHz. The VCO would get driven to its highest or lowest frequency, and possibly not even oscillate. The digital display would show a huge error, or no count.

One thing that hasn't been mentioned or asked if it's on all bands or just some, or one. If there is some minor instability in the VCO loop (or loop filter) the PLL would just undo the frequency error, at the expense of some phase noise, which wouldn't manifest itself as frequency jumps, but perhaps audible noise. A PLL can't stay locked and have a frequency error (If the reference is stable). The TS-820 PLL has two crystal oscillators (CAR and HET) which make part of the frequency equation. If either of those change frequency the final frequency that the VCO will get tuned to by the PLL will shift Hz for Hz. Also, of course VFO instability will cause this.

As I have a new to me 820 that I just un CB-ed and tuned the whole VCO/CAR, etc. (As well as fixed an intermittent 9V) I decided to conduct a pull-ability experiment. By removing the two 9V wires from the AV-AVR unit I ran the entire rig's 9V circuitry off of an adjustable bench supply. Here is the results on 10 M
Volt 820 Display Count Shift VCO freq VCO shift
8.25 29747x -3000 38.57985 +160
Frequency display was jumpy in the 100 Hz digit VCO seemed stable
8.50 297500 0 38.57980 +90
8.75 297501 +100 38.57976 +50
9.0 297500 0 38.57971 0
9.25 297499 -100 38.57965 -60
9.50 297498 -200 38.57960 -110

From this test I conclude that a 9V issue can't cause a 3 kHz shift in the TX or RX frequency. I assume that at 8.25 V the internal counter was not functioning correctly. Of course I wasn't about to try 14V on the 9V supply, but if the volt sensitivity is linear that would cause 700 Hz down shifts in the VCO, I'm pretty sure the rig quits working if the 9V gets much below 8V.

My conclusion is that the CAR unit or the VFO is acting up. The CAR has two crystals that are meant to generate a 3 Khz shift. Is there any chance the CAR unit is switching between USB and LSB? If it's happening on all bands than it's the CAR or VFO. If its on one the HET oscillator has a bad oscillator for that band, probably a mechanical intermittent connection issue that allowing it to still oscillate, but change frequency.

73 and good luck
KV4UW

Brian,

you may be able to try a small "fiber" washer. But, I would try and see where it was/is arcing.
You have may only have to loosen the assemble(the long screw) and move the small ferrule away from the offending area. I just got a bit over zealous with the "ink" and it completed a path
from the wafer finger foil trace to the ferrule/screw/nut. I could see where the problem was, and
just scraped away the offending ink...and made sure that the offending parts were as far away from each other as possible....in this case you don't have much to work with...1/32" of "slack."

Brian:

If the fire came from the deck closest to the PA cage your are dealing with 340vdc Driver tube anode voltage applied to the wiper of S1-7 wafer. You are going to have to pull the RF board and examine that switch under good lite and magnification as sounds like you have a track to ground. You may be able to see it without pulling that band switch vertical board again, but most likely will have to pull to fix it. Should be no reason to need any additional insulation or any place to put it. If there is a carbon track it will have to be 100% scraped away. Solvents wont touch carbon track.

I would look at the spacer on each side at 9:00 and 3:00 to see if the solder you applied at that rivet head/contact/trace isnt touching the spacer which is grounded. Might be able to remove the back hardware and pull those two spacers and examine the space there and remove excess solder and clean out any carbon track with the S1-7 board in place?

With RF board out take a good look at L36 plate choke and R38 resistor to make sure they are not discolored or burned. If it were me I would measure them but not sure if you can do that?

This bandswitch repair is not easy and requires lots of attention to detail and must have very clean brite metal and use small gauge solder and apply very sparingly. I think for the 1st timer it is easier to install very small jumper wire thru the rectangular window in the contact hair pin turn and tack other end to associated cleaned PC trace. Much easier to get these two places cleaned to brite metal. Not as pretty a repair, but I think easier to perform.

47892. TS 520S band switch cleaning

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-02-26 21:43:22 UTC
From: <jweigh@...>
Topic: 47892 Message: 47892

I'm getting ready to clean the switches of the TS520S with Deoxit and I have some questions.
1: The band switch(s) do not look to be removable as in the later radios without a lot of solder
removal. They are boards and not wafers. Will just a good spraying and small paint brush rubbing be
satisfactory, then canned air? Will Deoxit overspray have a bad effect on the boards below the switches?
2: Can all the other(rotary) switches on the front panel be done by just spraying into them as best as
possible then exorcizing them and then canned air?
3: I need guidance on lubing the front bearing of the VFO.
Is it as simple as removing the two screws on the front(after faceplate has been removed) and gently
sliding it off? Then what sort of lube to apply?
4: Lastly how much light oil should be put into the fan felt pads? I have a syringe as an applicator.

Thanks, tips or don'ts will be greatly appreciated.

Please Please DO NOT not apply liquid tape to your TS-530 band switch boards!!!!!!

You have yet to determine the root cause of the arc over.

You have yet to determine the extent of damage.

Perhaps if you lived on a deserted island thousands of miles from civilization and rig was your life line, but not as a matter of routine. Would you want a Kenwood service center to be applying Liquid Tape anywhere in your KW hybrid?

Jerry,

Yes, the 520 series is a bit different from the "newer' brothers.

1: As in everything, opinions vary, but I have used DeOxit D5 many times with no detrimental
effect on "other boards." I do not want to get into a lengthy argument about the pros/cons of different cleaners/lubes. Just make sure that all residue is gone/dry prior to applying power. I feel it is not necessary to apply the cleaner-in-question with an applicator..I just use the plastic extension tube.Use the minimum amount possible...rotate the band switch through its rotationnumerous times ..."blow off" with canned air...and repeat.
2: Yes...but I recommend exercising...exorcizing may require things we need not get into..hihi
Some members like to use "fader lube" after a cleaning of rotary pots..etc
3: Which "front bearing" are you referring to? As stated prior, there are many different opinions about what to use. I use a synthetic Teflon based lube. Terry-k9tw uses I think, some kind of high speed turbine oil. It should be light and non-contaminating.

4: The fan is removable. Remove fan. Use the above lube...saturate the felt and place the fan over a paper towel or something and saturate the felt...and let the excess drip back out onto the towel overnight. The amount depends on how long the felts have been dry...I've seen some that were rock hard.

I hope this has not created a "fecal matter" storm. So, let's help and not confuse.

Well, I took the band switch apart again. Getting pretty good at it now. It did not arc where I thought. One of the tabs had bent over near the bottom, must have happened during installation. It was not directly touching but hair thin close to one of the board terminals at the bottom. It was close enough it was arcing. Nothing was vaporized but the tab had black residue and a small shiny spot. Anyway, that has been fixed and the band switch reassembled. Tomorrow, I hope to try it again. I'm pretty certain I will not see flash again, just hope I did not damage anything else.

I do have another question. When the 3 variable plate caps are turned clockwise to the max, is it ok for the fins of the caps to rest on the capacitor frame?

Thanks Brian KB4MNG

The rotating plates are not resting on the frame. All three should fully mesh in sync. When you install chains on the sprockets you need to gently apply pressure on the movable plates to seat the fibre spacer strip against the fixed plates. By making sure all three movable plates are fully meshed when you engage the respective chains you are ensuring they open and close in unison assuming have close to equal tension on the chains and sprockets are not slipping.

On each Large set of movable plates you will see a brown fibre/phenolic bar or strip that serves too maintain the plate spacing and when fully meshed that fibre is what is contacting or very close to the fixed plates. On some radios that fibre strip also serves as a mechanical stop. Old AM radio 365pf tuning capacitors comes to mind.

There is a mechanical stop collar at the front end of the drive shaft on the outboard end of the brass coupler. That collar has a long machine screw in it that contacts a screw thread extending thru the front panel. If that collar isnt adjusted correctly it is possible that the plates will not fully mesh.

Terry K9TW.

Brian:

I forgot to mention that if you adjust the Drive control knob for full open on the movable plates (which you would not do in service) they can in fact touch the "frame" cross bar and that doesnt matter as you have to remember the rotating plates are the "frame" electrically.

The whole purpose of the rotor shaft wiper contact is to keep the rotating plates at same electrical potential as the frame. The fixed plates are suspended in the frame by fibre insulators. So the frame and rotating plates are one "plate" of the capacitor and the fixed plates are the other plate with air being the dielectric.

Expensive capacitors use low loss ceramic material like steatite supports for the fixed plates.

So you are correct the rotating plates can touch the frame at full open and that is ok. Just dont want them to be slamming against the frame and the stop collar addresses that.

I've just joined this group after having bought a really nice 830...I've been after one for a while. It came with a fairly scabby SMC low impedance dynamic microphone.

Apparently entry the MC35S (or MC30) is the best fist mic...and of course is the one Kenwood suggested ;)

Does anyone recommend an alternative fist mic...or is there anyone with a good MC35S they are willing to part with? I'm not keen on desk mics.

Thanks, Simon

Good News! I finally put the rf board back in and it appears to be working great. I've got power back on all bands, the receive is much better, and 10 meters has returned!

Couple of questions.

When I change bands, where the switch settles into the indent, the radio is dead. If you advance the switch towards 10 meters slightly the band comes in. Is there a way to do an alignment on the band switch where it works with the indent on the back switch. It does this on all bands.

The plate current is reading about 7 on all bands. It may dip very slightly but not enough to use. It works fine using a watt meter but the reading on the acutal 530 meter is no help. Where do I need to start looking on that issue?

Thanks guys, Brian KB4MNG

Brian,

Congrats on getting it up and(somewhat) running.

The problem you are having with the "detent" is not uncommon. I will say that you have the shaft/band switch wafers slightly mis-aligned with S-22(in the final cage), that's where the "detent comes from. This usually happens when the set screws on the band switch coupler are not correctly tightened/oriented during re-installation. Does your rig still have the old nylon band switch coupler?? If so...check for cracks at the set screws...very common problem. I suggest that you find a new brass replacement one, available through several sources. Please explain more about "the plate current is only 7."

Yes, it has the nylon piece.

If you switch to IP the reading is about 7 on all bands(7 on the s meter). If you adjust for a dip, it may dip very slightly but not enough to get a reading to tune the final.

Brian,

Are you in the "tune" mode when you see the shallow Ip dip?

You state that you "got power back." How much power and at what Ip?

You state that the Ip is about "7" on the "S" meter..you may want to check that you are using the correct meter position..."7" on the "S" meter when meter selector is set to Ip equals about 150mA

Nominal power output should be around 100 watts at around 225-250mA or so. The mA reading may very according to the value of the final amplifier tubes cathode resistors. Watts output may be slightly lower on 10 meters.

Your driver tube, the 12BY7A, should be able to provide full ALC swing of the meter on the highest band. If not it may be in the early stages of getting tired. Tune rig up for max power.
In CW mode key rig and watch for falling drive after a few seconds of key down. If drive fall off, your driver tube is weak and going bad.

Tune up as above. Key down, watch the Ip. If it goes up to nominal value...then falls off, your
finals are going bad.

A broad, shallow Ip dip could also indicate finals that are going bad

Brian,

With the 530 in transmit and tuning the transmitter final amplifier, there is no such thing as dipping S Units. Placing the meter switch to IP, keying the transmitter, the meter is displaying final tube "cathode current" on the "top scale", not "S Units"!

I dont recall anyone asking Brian if this "plate current dip" problem is new since he did the bandswitch repair or was it behaving this way before the repair.

He needs to do two things:

1. Align the bandswitch and perhaps replace the cracked white nylon coupler
2. Open his Operators Instruction Manual to around page 17 and READ and literally follow the procedural steps to load his TS-530. He needs to place emphasis on the NOTE that follows Step 9 and look at Table 4-1. The NOTE is there for a reason.

If he does that he will see that the dip in TUNE mode will be small. There is no reason to load any KW Hybrid using the Dip and Load method. The proper way to load a Class AB1 linear amplifier is to load for maximum RF output power without exceeding maximum plate current (265ma). This is why KW engineers provided the RF relative power meter position. If they had not intended operators to tune for Max output they would have just provided IP position and not wasted money on rf detector components.

OK to make that initial plate current dip in TUNE mode and repeat it in CW mode so you know the Tank is close to resonance and wont have to worry about overheating from long off resonance key down times. After that need to use the RF meter position and alternately adjust the Plate Load and Plate Tune capacitors for maximum RF relative power or maximum RF output power on your external wattmeter.

TABLE 4-1 just needs one last step added to it. Something like....."When done adjusting Plate Load and Plate Tune for maximum relative RF power (approx 100 watts) place the meter selector switch back to IP and make sure not exceeding 265ma." If it is then close the plates of the Plate Load cap slightly (turn CCW) and re-adjust the Plate Tune cap.

This is so simple it becomes childs play. Why make it so hard? Can be done in literally seconds and if you have external wattmeter have best of both worlds as can leave meter switch in IP and when done loading for maximum RF output can see at a glance if exceeding maximum IP.

This is not a Class C CW transmitter.

So Brian is this a new development?

Brian:
Not saying you dont have a problem with your TS-530. Just wanted you to be loading it per the manual for starters and see how that works for you. Curious where you have the Plate Load control set at prior to loading the rig?

Before you peak the ALC indication in Tune mode and then place meter in IP and dip the plate current try this:

1. Deliberately pre-set the Plate Tune cap off of the painted white locator for the band that you are going load on. I do all test loading on 20 meters around 200 on the VFO. This is where KW does their testing and TX level diagram developments. So set the Plate Tune control for 18 or 21. Can do on other bands but give this a try.

2. Make sure the Plate Load cap is full CCW position. This places the plated fully meshed and should be the point that you see the biggest change in IP as you rotate the Plate Tune capacitor thru its range. If you pre-set the Plate Load cap to approx 1100 or so you will essentially have picked up a big junk of load immediately as you have the plates unmeshed which means lower capacitance which means much higher capacitive reactance Xc which means much more Tank circ current transferred to the dummy load and not flowing thru the Plate Load cap. This means very little dip remaining.

The point is if you pre-set the Plate Load and Plate Tune caps too precise you can have very little initial plate current dip.

I normally recommend that people start with the Plate Load cap fully CCW (plates meshed) until they get use to loading. They feel better if they can see this all important dip in plate current. Later you will learn you dont have to pay much attention to it at all. Most folks in short time are tuning/loading on the fly as they chase DX and QSY all over the band.

I have a 530-S which had multiple problems.It was over my head so I looked for recommendations for repair work. I am sure that there are some fine repair shops but I chose our own reflector member Terry K9TW. I chose him based on other recommendations and the fact that he is active here helping others and seems to have a good knowledge of our radios.

After we chatted about the radio he gave me a detailed outline of his services and his prices. His prices were very reasonable his services were made crystal clear. I sent him the rig following his direction. When the rig arrived he informed me promptly and got to work. It was finished in a few days and shipped back to me. His charges were EXACTLY what he quoted me. I needed some parts which he obtained for me at very reasonable prices and even gave me a trade in allowance on one. He did not order or install parts until we had discussed it. He shipped it back to me packed like it would survive a Fed-Ex aircraft accident.

The rig has NEVER worked so well. It is clean and crisp in it's operation and I am very happy in every respect. I get better signal and audio reports that ever before.I give him a 5 Star rating in every way, I would not say that to all of you if I was not totally satisfied.
Best,
Kevin

47914. TS-520S - Marker signal calibration issues

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-01 03:44:13 UTC
From: Wes Will
Topic: 47914 Message: 47914

Been working via email with one of the newer members of this list, and he is in the process (now that the thing is working at all) of re-aligning and re-peaking everything. Got to the "marker generator" section of the operator realignment and there we stick.

He puts his frequency meter on the MO point, and the marker (which is audible) gets dragged down, will not synch to be read by the freq counter, and when he pops on the o-scope it just shows really random junk. No waveforms, just static. And the marker (audible when no test leads are attached) fades out and becomes very weak if not gone. I've never seen a freq counter load a circuit that much before, honestly.

Question is, is it the counter loading it, or that the marker signal generator is so weak or so close to not being an oscillator perhaps? Is the problem the test gear (I don't think it is), or is it the marker circuits? I've never dealt with one of these rigs before getting one of my own, so I'm NOT going to more than speculate here. I'd guess the marker was weak, but as I said, that's speculation.

In the group gestalt experience, how often does a simple circuit like the marker oscillator go bad? Ever? Often? Or is this another, "I've never seen one of those go bad before in thirty years" kinds of things?

Opinions, please? Thanks.

(And anyone who happens to want to point me at disassembly instructions to get at the crystals on the oscillator coil board (X44-1160-00), that is, if the exploded drawings in the service manual aren't all there is, I'd be appreciative. Are there any 'gotchas' to getting to it? I'm not too proud to ask for help. I'd like to do it right ONCE, rather than botch it up and have to re-do it.)

Topic: 47901 Message: 47915

Simon,

I'm far from an expert on the 830S, although I do own one which is not on the air yet. The manual states the 830S will accept both high Z and low Z microphones. The standard Kenwood matching mic (MC-50)is often touted, as are the Shures (not "Sures") of that vintage, but I would think that a lot of mics with similar frequency response would work OK. I have not seen any actual comparisons of mics. A standard CB mic would have a frequency response of about 100-5000Hz, maybe plus or minus 3dB. The Kenwood MC-50 is rated at about 100-10K Hz, but IDK the sensitivity.

If I were you, before I went on a quest for one mic that was the Holy Grail, I'd request actual user experiences and try just a generic mic and see how your listener reports go. In my case, I have a Shure desk mic, but my hearing aides would work better with a set of earphones, so I'll be trying a set of earphones with a boom mic to see how this stacks up against the Shure and speaker or Shure and a set of earphones.

A wiring diagram for the four pin connector should not be hard to come by in this august group.

Best Regards,
Roy Kersey

Wes

Are you trying to do Step 12 of the TS520S service manual?

If so Counter input Z may be too low to connect to MO. With a O-scope will need to use the 10X probe and wave form will be harmonic rich and with most older Scopes is not good way to adjust the xtal trimmer. Especially if it does not directly display frequency and you are trying to count horizontal divisions and apply 1/T = Freq method.

With some freq counters that have good pre-amps you can make a "sniffer" loop to read the oscillator without loading it.

If you cannot do it with Freq counter then use 15mhz WWV signal and zero beat it. Pick a time when WWV is strong and not a lot of QSB on signal. It is not easy to get true "zero beat" or exactly 0 hz. beat note as your receiver audio response isnt that good all the way down to 0 hz. Some folks intentionally tune off freq to approx 1000 hz and try to match the Marker tone to that. I dont have that good an ear. With a good strong WWV signal and a little practice can get it pretty close.

Today with all the new DSP rigs on the air many of the net operations on the bands are spot on frequency. Maybe find one that is on even 25khz multiple and tune there for natural voice and then disconnect antenna and dont touch VFO knob and zero beat Marker signal there.

Wes

I forgot to mention that you may want to place AGC to Fast and use the S-meter flutter to help you not only hear but see the zero beat. Can swing VFO toward zero beat and tune through it until hear beat on the other side and then come back approx 1/2 way to as slow a S meter needle flutter you can get (split the difference). Probably best can get is approx 50 hz or so, which should be good enough.

Thanks to everyone who help me with the microphone EV 638 (WA2LBI, W5RKL).
Now my question is related to the transmission and reception frequency. The other stations reported to me that I moved from the center frequency at 200Hz and I hear the other stations, above 200Hz, from the center frequency.
I am using the RIT / XIT control to momentarily solve the problem, but I want to know, how I can make an adjustment to correct the problem.
Thanks in advance.

But DO realize that if you UNPACK carefully you now have a pair of boxes fit to ship it in AGAIN if you ever need to.

Several times, possibly, until the Gorilla Unit in one of the shipping manglers gets down and dirty on it. Then it will have done its job, and "given that last full measure of devotion" to your rig, and you'll have to replace the boxes.

I have a shipping box for some heavy items with crushable cardboard wedge things, a LOT of packing foam, and several meters square of bubble-pack. I can ship a MOOSE in that box if I have to and expect it to arrive intact. It has paid for itself (the two boxes and the crush-wedge things alone cost me almost sixty bucks!) several times over.

So be sure to keep the boxes he sent! They're gold. Well worth the space in the attic or where-ever.

Wes,

I also have tried to follow the procedure for adjusting the marker signal calibration. It did not
work for me. I used the "zero beat" method with WWV and the "wavering needle" and can come rather close and maintain "good amateur practice." People have to remember that these rig were state of the art "analog" rigs. After maybe 40 years or so..,they may be off a few hundred Hertz.

As far as removal of
the osc board:

I am going on my notes from a previously owned TS-520SE

Band switch to "JJY/WWV ...loosen screws that are facing UP
""""""""" "" "7" loosen screws that are facing UP

These screws are at the end of the band switch shaft connected to the band switch coupler

Pull knob and shaft staright out towards front of rig DO NOT ROTATE!!! My notes fail to indicate if you need to have the face plate removed...but I do not think so.

PLEASE...take pictures or make good notes...just to make sure

You should now be able to loosen and remove the two small screws towards the front of the rig that help hold stuff together. Remember that there are also a couple of small split-washers there too. You should now be able to slide the long screws towards the rear of the rig,
paying careful attention to the spacer ferrules between the different boards. You may have to
move some wires out of the way...to get some space...Also, you'll have to get your soldering iron warmed up...and some braid/solder sucker to unsolder each side of the board by the two screws that are holding the metel shield in place.

Note: this procedure is done with the rig OFF, UNPLUGGED, AND FREE OF ANY VOLTAGE(standard warning/disclaimer)
Covers removed, bottom up, front facing you.

Let me know if you may need some more info

Already saw that one, thanks. It's already out, so wasn't a lot of help getting started. I'm dealing with other things at the moment, my mother passed away about 0200 this morning, so I won't be soldering much for a few days.... Though perhaps it would be good therapy. Her passing is, shall we say, unfortunately not something myself and my brothers are actually mourning. It was that kind of deal, unfortunately. But the wheels still have to turn and we've a lot to deal with to wind up her affairs.

If I get in a bind I will get back on here, but I hope it just (for ONCE) just happens without hitches. And there will most assuredly be pictures, as well as MARKINGS on the switch and parts as they come out. I'm not in the mood for more trouble from a radio. It's just NOT on the list for this month.

My TS-820S has developed an issue where I lose drive after the rig has been on and warmed up for awhile.
I can obtain normal drive and tune on each band when I first turn the radio on (using the normal start up procedure), but within a few minutes (about 10 to 15 minutes) I lose all drive and output power. I still have normal idling current even after the output power goes away. The driver and final were new last year.

The covers are off, can anyone point me in a particular direction?

Tim:

1. Does receive stay "normal" at this time?

2. Does the display blank?

3. What test gear do you have? Can you measure RF drive voltages and DC voltages?

4. If you flip the SG switch off at this time and turn CAR Level pot full CW and flip to Send and turn Drive control thru its range do you see any ALC indication at any time on any band?

5. If Display blanks check for VCO signal at TP-1 on the RF board. Should be approx 1.0 rf volts. If Display stays on measure RF drive level at MD on RF board. Should be approx 2.0 rf volts. Need O-scope, RF millivolt meter, or VTVM and RF probe.

6. Push and pull on the Driver tube with rig keyed. Becareful and not burn yourself as heat shield will be hot. May be a bad solder connection at the tube socket. Wiggle the Molex connectors on the RF board.

Hi guys,
It was working, and I pulled the PLL board to de-flux & clean the board in Isopropinal alcohol. Reassembled back to the 530 chassis, and it went unlocked (blank freq display). I haven't troubleshooted the PLL board yet, so I'm reading up on how it works.
Anyone have a few tips on what to check with the O-scope to start with? I'm thinking there must be some solder joints that need re-soldering or something simple like that.

Well, out, swapped the crystals, and back in again. That band switch is a nightmare.

For the record, as I just did it, here is the procedure to pull the oscillator board to replace the CB band crystals with the 10-meter crystals that ought to go in there:

1) UNPLUG THE RADIO FROM THE MAINS POWER. Remove antenna and key/microphone connections. Remove any ground connections.

2) Remove both top and bottom covers. Pull the speaker connector off of the speaker and tuck the speaker wire back out of the way somewhere, so the edge of the chassis doesn't nick or cut it. CAREFULLY DISCHARGE THE HIGH VOLTAGE / PA SECTION CAPACITORS. Use a chicken-stick/zap-stick whatever you call the thing.

3) You will initially be working with the radio UP-SIDE DOWN, FRONT BEZEL TOWARD YOU. Use solder-wick braid, a suction bulb, or a desoldering vacuum tool to remove all of the solder on the sides of the oscillator board. If you have a higher-wattage iron, this might be the place to use it to get the solder to flow quickly, but BE CAREFUL not to over-heat the circuit board.

4) Rotate the band switch until BOTH of the set screws are accessible, from an angle to either side of vertical. Doing one side while the switch position holds it straight up (WWV position) and then rotating it until the other one is straight up (40-meter position) is ASKING for the whole shootin' match to slip out of line, one set screw will NOT really hold the thing in place.

5) Loosen the screws in the connector sleeve which hold the front half of the shaft in place. Leave the two rear-most ones which hold the back

half of the shaft alone. You must also be EXCEEDINGLY CAREFUL NOT TO ROTATE THE BAND SWITCH SHAFT AT ALL FROM THIS POINT ON. NOW would be a good time for pictures and marking the wafers on ALL the segments to be CERTAIN they do not shift or get out of line.
6) Remove the two small screws which hold the shield behind the oscillator board. By flexing this thin metal shield VERY slightly, you will be able to pull it upward and out of the way. You -might- be able to get this done leaving this shield alone, but the extra room never hurts.

7) Remove BOTH front nuts and split washers from the long screws holding the switch wafers in line.

8) Remove the right-hand rear nut and lock washer (as you look at it from the front) on the right-hand side long bolt. Slide the solder lug off of the bolt. It is connected to the small coil adjacent to that long bolt. Remove the plastic spacer, noting which way the smaller end is located, to accomodate that solder lug. You do not have to touch the left-hand nut and washer. Best to leave it alone.

NOTE: Tools for this evolution thus far (the nuts) are going to be a bugger. You CAN use a pair of needle-nose pliers to un-screw the nuts, but it means a metric buttload of tiny little bites (about a sixteenth of a turn per movement, which gets OLD quickly). A VERY SMALL adjustable (crescent) or small open-end wrench help a lot.

9) Once the nuts and washers are off, slide the long bolts rearward, moving any wires out of the way, until the front-most spacer tubing pieces can be removed from both long bolts. Put them aside carefully. Keep sliding the bolts backwards until the second spacer tubes can be removed. STOP RIGHT THERE.

10) SLIDE THE BANDSWITCH SHAFT OUT until it clears the oscillator board. The front switch wafer will need to be slid carefully along as the bandswitch shaft moves out. Once it clears the board itself, STOP. Do not remove it all the way, just leave it sticking out, and DO NOT TURN IT AT ALL. Don't give in to the temptation to rotate it slightly or "wiggle" it side to side while withdrawing it from the wafers and boards. JUST DON'T LET IT TURN.

11) Carefully flip the radio over and locate the four wire-wrap posts which are the only things now holding the oscillator board in place. If the board has been out once already to be mangled for CB, the wires connecting the four posts to the RF board have undoubtedly been SOLDERED back on. If this is the first time or if the original modification was done by someone with a wire-wrap tool, it will be wire-wrapped. Whichever way it is, disconnect the four wires, either un-wrap or de-solder them.

12) Flip the radio back over. The board will now slide straight up into your hands.

13) The CB mod involved only crystals X7 and X8. Desolder the CB band 36.xxx MHz crystals, and replace them with the 37.xxx MHz 10-meter crystals. The lower frequency of the two is X7, the higher one is obviously therefore X8.

14) Reverse the entire procedure, slipping the board back in, resoldering the 4 wires (or re-wire-wrap them using NEW WIRES ON BOTH POSTS.) Do NOT try to re-wrap the old wire back onto the post it came from. Soldering it would be MUCH better than trying to re-use 4 cm of wire. Either wire-wrap from both posts again or solder the original wires back on.

15) Push the band switch shaft carefully BACK into all of the wafers, making sure to guide that front-most one. Remember to do this WITHOUT ROTATING ANYTHING!!! Once it is seated fully to the rear through all the wafers and into the coupler, CAREFULLY re-tighten the set screws. (If you've got a metal replacement coupler, and I recommend them highly, NOW would be the time to put that sucker on.)

16) Press the long bolts forward, back through holes in the front wafer, and put the nuts and washers back on. Don't forget to put the solder lug back on that right-rear long bolt when that goes back together. Watch which way the plastic spacer goes so as to grab the solder lug and hold it snugly. Make sure the wire from the coil isn't pinched in anything and runs nice and straight to the solder lug.

BE CAREFUL TO NOT NOT NOT OVER-TIGHTEN THE SMALL NUTS!!! Get them good and snug, enough to fully compress and flatten the lock washers, then STOP!! This is NOT the place to play He-Man and torque these nuts down hard. If you wish, once they're snug and firm, put on a TINY drop of LockTite. I did. (NOT the permanent sort!!)

16) Re-align the radio, using the procedure from the board posts or the service manual, mostly the same thing but with the occasional hint or 'trick' in the board messages to make things easier or more exact with limited equipment. (I stopped at this point, I'm planning on aligning it tomorrow, or at least getting a good start. I -did- power it up and check to see that everything worked, and that I could receive on all bands. The band switch needed a couple of full turns to excercise it and get things back in line, but once I carefully ran it full-rotation in both directions, SLOWLY, everything was fine. It was good to see "28.640" and "29.140" on the freq counter when I ran it up to those bands, instead of "27.something...")

I was right, the detailed work was good for my rather upset mind. I needed the distraction. All in all, it was very straight-forward, if requiring much pains-taking. Anyone with some patience and the crystals in hand ought to be able to do it fairly easily.

Comparatively VERY easily, if your hands work well and you aren't fighting your own arthritic fingers when getting tiny nuts and washers back on bolts in tight quarters... (Magnetized tweezers are ASSUREDLY your friend here.)

Hope this description helps someone down the line.

Tim:

Before doing anything I would pull and clean the Aux or TR relay as some call it. This is not the Antenna TR relay. The relay is socket mounted about center bottom next to two grey vertical can electrolytic filter caps.

Clean the NC and NO contacts with strips of copy paper wetted with Deoxit by pulling the wetted paper thru the contact as you apply lite pressure to the armature or movable leafs. Should see black streaks on the paper. Do this multiple times. Can also clean the antenna TR relay and swap the relays.

If that doesnt help then may be able to use the Eico VTVM and demodulator probe to take the RF drive level voltages. Would also want you to measure ALC bus voltage at RF board on Conn RF-3 Pin 6 and see if it is stable there. Cant measure it with your VOM, but may be able to measure it with your EIco VTVM. It will pull it down, but should be steady at Pin 6.

Report back after relay cleaning.

Hi group,

I have picked up an MC-50 desk microphone from a junk sale to use with my TS-520S. Listeners say it has too much base , (I have a deep voice) . I guess putting a capacitor in the audio line would work. So has anyone done this? And what value cap did you use? Normal microphone is an MC-35S hand mike, and I get good reports.
Thanks,
John

John,

It's possible your MC-50 microphone impedance connection on the microphone is not set properly. The TS-520 has a high (50K ohms) microphone impedance requirement and the MC-50 impedance plug connection, see below, must be connected at the microphone for "High Impedance".

The cable plug from the microphone stand to the microphone AND the microphone socket both have a "RED" dot. Connect the microphone cable plug so both RED dots match which will make the MC-50 have a high impedance.

The cable plug I am referring to is NOT the cable plug that plugs into the TS-520 but rather the plug that plugs into the microphone from the microphone stand.

Jan:

Didnt see any responses? Not sure why you are pulling and cleaning PLL board? This board as you know is on bottom of rig. It doesnt see much dust and certainly not the oily greasy dust that would cling to a board. I guess it depends on environment it has been in. Perhaps a smoker?

Much more important than cleaning KW hybrid PC boards would be detailed inspection of all Molex connectors pin soldering if you have to pull a board when troubleshooting has indicated you need to replace components on the board.

The way I inspect the pins is to reconnect the plug (I have spare wire harnesses) to seat the pins and then with brite lite and magnifier I gently rock the connector body back and forth and watch for pin movement or for circumferential crack 360 degrees around the pin. You cannot simply try to reheat these. Need to remove all old solder that did not wet to the pin, lightly file the pin to clean off the oxidation, and then resolder. Some times if the connector body has undergone many plug and unplug cycles the PC trace has cracked at the Pin pad and now you have a intermittent that is hard to find.

I dont recommend pulling boards to clean them with alcohol or any solvents when there is nothing wrong with the board. All you do is risk inducing latent fault in these old rigs. This is especially true of the PLL board that is a very reliable board.

As to your PLL unlock it sounds like you may have lost VFO input to it. I would try plugging and unplugging Molex connector 5 and measuring the VFO input. Should see approx 200mv. Can also sub the signal with RF sig gen and see if rig comes alive. Since you disturbed the PLL board most likely problem is there, but could also be dirty FIX switch or Mini-din switch in the Remote VFO socket. If not Conn 5 then exercise these switches.

People have to remember that these rig were state of the art "analog" rigs. After maybe 40 years or so..,they may be off a few hundred Hertz.
>
> As far as removal of
> the osc board:

Well, out, swapped the crystals, and back in again. That band switch is a nightmare.

For the record, as I just did it, here is the procedure to pull the oscillator board to replace the CB band crystals with the 10-meter crystals that ought to go in there:

1) UNPLUG THE RADIO FROM THE MAINS POWER. Remove antenna and key/microphone connections. Remove any ground connections.

2) Remove both top and bottom covers. Pull the speaker connector off of the speaker and tuck the speaker wire back out of the way somewhere, so the edge of the chassis doesn't nick or cut it. CAREFULLY DISCHARGE THE HIGH VOLTAGE / PA SECTION CAPACITORS. Use a chicken-stick/zap-stick whatever you call the thing.

3) You will initially be working with the radio UP-SIDE DOWN, FRONT BEZEL TOWARD YOU. Use solder-wick braid, a suction bulb, or a desoldering vacuum tool to remove all of the solder on the sides of the oscillator board. If you have a higher-wattage iron, this might be the place to use it to get the solder to flow quickly, but BE CAREFUL not to over-heat the circuit board.

4) Rotate the band switch until BOTH of the set screws are accessible, from an angle to either side of vertical. Doing one side while the switch position holds it straight up (WWV position) and then rotating it until the other one is straight up (40-meter position) is ASKING for the whole shootin' match to slip out of line, one set screw will NOT really hold the thing in place.

5) Loosen the screws in the connector sleeve which hold the front half of the shaft in place. Leave the two rear-most ones which hold the back half of the shaft alone. You must also be EXCEEDINGLY CAREFUL NOT TO ROTATE THE BAND SWITCH SHAFT AT ALL FROM THIS POINT ON. NOW would be a good time for pictures and marking the wafers on ALL the segments to be CERTAIN they do not shift or get out of line.
6) Remove the two small screws which hold the shield behind the oscillator board. By flexing this thin metal shield VERY slightly, you will be able to pull it upward and out of the way. You -might- be able to get this done leaving this shield alone, but the extra room never hurts.

7) Remove BOTH front nuts and split washers from the long screws holding the switch wafers in line.

8) Remove the right-hand rear nut and lock washer (as you look at it from the front) on the right-hand side long bolt. Slide the solder lug off of the bolt. It is connected to the small coil adjacent to that long bolt. Remove the plastic spacer, noting which way the smaller end is located, to accomodate that solder lug. You do not have to touch the left-hand nut and washer. Best to leave it alone.

NOTE: Tools for this evolution thus far (the nuts) are going to be a bugger. You CAN use a pair of needle-nose pliers to un-screw the nuts, but it means a metric buttload of tiny little bites (about a sixteenth of a turn per movement, which gets OLD quickly). A VERY SMALL adjustable (crescent) or small open-end wrench help a lot.

9) Once the nuts and washers are off, slide the long bolts rearward, moving any wires out of the way, until the front-most spacer tubing pieces can be removed from both long bolts. Put them aside carefully.
Keep sliding the bolts backwards until the second spacer tubes can be removed. STOP RIGHT THERE.

10) SLIDE THE BANDSWITCH SHAFT OUT until it clears the oscillator board. The front switch wafer will need to be slid carefully along as the bandswitch shaft moves out. Once it clears the board itself, STOP.
Do not remove it all the way, just leave it sticking out, and DO NOT TURN IT AT ALL. Don't give in to the temptation to rotate it slightly or "wiggle" it side to side while withdrawing it from the wafers and boards. JUST DON'T LET IT TURN.

11) Carefully flip the radio over and locate the four wire-wrap posts which are the only things now holding the oscillator board in place. If the board has been out once already to be mangled for CB, the wires connecting the four posts to the RF board have undoubtedly been SOLDERED back on. If this is the first time or if the original modification was done by someone with a wire-wrap tool, it will be wire-wrapped.
Whichever way it is, disconnect the four wires, either un-wrap or de-solder them.

12) Flip the radio back over. The board will now slide straight up into your hands.

13) The CB mod involved only crystals X7 and X8. Desolder the CB band 36.xxx MHz crystals, and replace them with the 37.xxx MHz 10-meter crystals. The lower frequency of the two is X7, the higher one is obviously therefore X8.

14) Reverse the entire procedure, slipping the board back in, resoldering the 4 wires (or re-wire-wrap them using NEW WIRES ON BOTH
POSTS.) Do NOT try to re-wrap the old wire back onto the post it came from. Soldering it would be MUCH better than trying to re-use 4 cm of wire. Either wire-wrap from both posts again or solder the original wires back on.

15) Push the band switch shaft carefully BACK into all of the wafers, making sure to guide that front-most one. Remember to do this WITHOUT ROTATING ANYTHING!!! Once it is seated fully to the rear through all the wafers and into the coupler, CAREFULLY re-tighten the set screws.
(If you've got a metal replacement coupler, and I recommend them highly, NOW would be the time to put that sucker on.)

16) Press the long bolts forward, back through holes in the front wafer, and put the nuts and washers back on. Don't forget to put the solder lug back on that right-rear long bolt when that goes back together.
Watch which way the plastic spacer goes so as to grab the solder lug and hold it snugly. Make sure the wire from the coil isn't pinched in anything and runs nice and straight to the solder lug.

BE CAREFUL TO NOT NOT NOT OVER-TIGHTEN THE SMALL NUTS!!! Get them good and snug, enough to fully compress and flatten the lock washers, then STOP!! This is NOT the place to play He-Man and torque these nuts down hard. If you wish, once they're snug and firm, put on a TINY drop of LockTite. I did. (NOT the permanent sort!!)

16) Re-align the radio, using the procedure from the board posts or the service manual, mostly the same thing but with the occasional hint or 'trick' in the board messages to make things easier or more exact with limited equipment. (I stopped at this point, I'm planning on aligning it tomorrow, or at least getting a good start. I -did- power it up and check to see that everything worked, and that I could receive on all bands. Jan:

My response was for a TS830. Sorry I didnt notice you were working on a TS530. My counsel to check all molex pin soldering stands any time you have to pull a TS530 or TS830 PC board to replace components.

As to present condition after re-installing the board for starters I would still make sure that you have good VFO signal to the TS530 PLL board.

Terry

Has anyone formulated an idea as to why are all
these broken traces starting to show up? Maybe
the board is flexing with temperature changes in
the shack, or shipment as it moves from one owner
to another. Finally after the 30-40 year life
span is starting to take it's toll?

Mark,
I'm noticing the solder joint problem particularly on my 530's boards
(and maybe now on the 530's PLL board), and somewhat on my 830's boards.
I resolder all the molex-PCB connections. I find some of them just like
what Terry described, as they would rock back-and-forth!
Both my 530 & 830 were dead in both RX/TX when I purchased them. They
are coming back a little at a time.

Not to dispute what you are saying about pulling the boards to clean them but there can be issues with the pin connectors. Over a period of time a thin film of oxidization builds up on the pins and and the female connector that can't be seen, and can have an affect on making a good connection. This can happen especially if a rig has been put away for a long period of time not being used and stored in an area where there are drastic temperature changes.

I recently purchased a Kenwood TS 820 that had problems because of that very reason - the led display wasn't working at all, along with the unit not transmitting fully on some of the upper frequencies. What I did was carefully remove the boards and coated the pins using a q-tip with a drop of oil on it - just enough to coat the pin not saturate it. . Did this to just about all the boards -

Once I finished turned the unit on and the led display lit up and has been working ever since. I can now transmit full power on all frequencies.

With regard to the solder joints coming apart where the pins are connected, it could be a quality control issue during the manufacturing process and maybe some of the Kenwood rigs had better quality control standards then others.

But, I will have to say after I cleaned all the terminal pins on my unit it works superbly .

47949. Wire size calculation

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-03 18:39:49 UTC
From: Mike W5RKL
Topic: 47949 Message: 47949

How many times have you found the single layer RF choke in your Hybrid that was bad, overheated and needed to be rewound but you didn't know the wire gauge? I've seen this question a few times on the group. You can easily determine the gauge of the wire by simply using the following formula.

First, you must count the number of turns on the RF choke form, take you time.

Next, you measure the length of the coil, be as accurate as you can, using a simple ruler.

Next, you use the following formula to calculate the gauge of the RF choke wire.

WG = L / T

Note:

"WG" is the unknown wire gauge
"L" is the length of the coil wound on the screw driver shaft
"T" is the number of turns

I don't have a single layer RF choke but I do have a few smaller coils, one of which I had to rewind to fix a problem in a Johnson Messenger One I was converting to 10 meters. The coil had overheated, just like some of the Hybrid final amp RF chokes have done, but I didn't know the gauge of the wire.

The coil in question had 24 turns and the coil length was 5/8".

I first converted 5/8" to a decimal, .625 (5 / 8 = .625). I then plugged the numbers into the formula as follows:

.625 / 24 = .026

or 26 gauge enamel magnet wire. I purchased some 26 gauge magnet wire and rewound the coil. The coil fit perfectly in the same space as the original coil and fixed the problem.

I obtained the information on determining wire gauge at the following link while reading up on rewinding/rolling my own power transformers.

It is due primarily to this belief that you need to routinely plug and unplug and clean the connectors on the TS530 and TS830 rigs and improper pulling of the plugs off the connector body. The connectors on the 820 are different and more robust but not without jeopardy. Easy to crack a board on them.

These connectors are not meant to be frequently exercised. I see this mostly on the IF 530/830 board which is pulled more often than any board in the rig for filter selling and filter changing. I also see more cobbled up wire jumpers and bridged solder attempts at repairs on the IF board. I dont have any boards like that in my rigs and dont do that to customers radios. When I find them in customers rigs I send pictures to them and ask them what they want me to do. If I cause the failure I buy a good replacement board from Bob Mansker and install it and eat the cost.

The problem is people do not know how to pull these plugs. You cannot simply grasp and pull straight up without risking pulling the plug and mating connector body right off the board. Also you cannot rock the connector back and forth sideways very much as you pull upwards without risking cracking the trace to pad transition on the foil side of the board. The way you pull is by pulling slightly at each end of the connector body and then grasp in center and pull upward and if you apply any rocking action at all do so in the end to end plane and not side to side plane.

I commonly find molex connectors on customers rigs that I can grasp and rock side to side. If you have any of those presently on your rigs you have a potential problem that needs to be addressed. Should be very little side to side motion if all the pins have good 360 degree filet solder weld.

Topic: 47930 Message: 47951

I have been doing this for 10 years plus now and more than 120 units across the bench and I have yet to fix any operational problem on a TS530 or TS830 PLL board by cleaning it with denatured alcohol or everclear or lacquer thinner or placing it in the dishwasher.

I did not say that dirty molex connectors could not be a source of intermittent problems. Any time you pull molex connectors on these boards you must be aware of the risk. Very easy to induce an immediate failure or a latent failure and the latent ones can be a pain to find. These are not heavy glass G10 boards. I have seen more than one TS820 with a cracked corner on an RF board or a cracked FIX board. Common for the 820s due to different design to be bonded and require much more force to unplug.

I understand wanting to clean oily greasy dust off the PC boards if you are restoring a rig that is a mess. You just have to go in to that with eyes wide open. Cleaning boards as a matter of routine to address operational problems in my experience very seldom results in a fix especially so with any of the bottom mounted boards.

There will always be differing opinions on this subject. Your rigs do as you want.

Thanks for your input on this. The manual does state that it will use low and high impedance mics and I currently have a Shure 414B hooked up to it. The MC50 seems to be the mic many people use but I prefer a fist mic...such as the MC35S or MC30. I'll keep an eye out for one...they do turn up occasionally.

The TS830S...and I guess the 830/520/530 too...sound great.

Personally, I prefer these old rigs...and some older tube gear...to the modern marvels.

Although I am fond of my IC7400 :)

Cheers, Simon, M5POO (sorry I forgot the callsign last time)

Suggest you check coax jumper J1. This is a grey miniature coax that routes VFO signal to mixer Q29 in lower left hand corner of the Schematic. Without it you will lose the CON signal. I have found the center conductor at Q29 end of this short jumper not soldered more than once.

Just be very careful soldering on any of the KW hybrid boards. Very easy to lift a foil.

Two schools of thought here as well. Some say go in hot and get in and out quickly and others say dont run iron very hot and use only as much heat as needed. I tend to be in the camp of going in hot but have had bad experiences using either method. Key for the Molex connector pins is to remove all old solder and clean the pin. Once you have brite metal very easy to resolder and get it to wet to the pin. I usually do this with the plug installed so that the pin remains fully seated during the soldering.

John,

Some Ops have reduced the bass (increased the highs) of their MC-50 (and MC-60) by wrapping thin card stock around the mic element inside the mic head. Others have performed a crude implementation by placing the card/tube on the outside of the head. The internal version is preferred.

You remove the head by CAREFULLY using hot air to heat the joint between the base of the head and the top of the handle in order to melt the glue used to lock the threads. Wrap a rag around the handle while heating and periodically try to unscrew (counter clockwise) the head. DO NOT USE any type of pliers, clamps, etc. or you will damage the mic parts.

Once the head has been removed cut to size a piece of thin card stock that just wraps around the mic element without overlapping the ends of the card. Be sure the height of the card is trimmed so the head can be reassembled without crushing the card and possibly damaging the element.

Good luck!

I put one layer of electrical tape around mine,
through trial and error testing.

I closed off 1/2 of the slots, leaving the 1/2
nearest the front of the mic open. That split the
difference between highs and lows. Seems to work
ok for me. Once you get the proper amount of
slots closed off, based on your particular voice,
then you could substitute the electrical tape for
heat shrink of the correct diameter to make it look at little better.

Get a contact with someone that knows your voice,
and just keep closing off more of the slots until you are spot on.

47958. Hybrid Net Update + Dayton Forum 2014

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-03 22:40:01 UTC
From: Mark Gilger
Topic: 47958 Message: 47958

Dayton Hamvention Kenwood Legacy Forum:
This year will be the first year for the Kenwood
Hybrid Legacy Forum to be held at the Dayton
Hamvention. The forum will be Sunday May 18th.,
room #2, 10:30 □ 11:30. The following preliminary agenda has been proposed:

```
* History of the legacy products.
* Resource help with parts, documentation, etc..
* SDR integration into the legacy line.
* Rewinding a TS-830 L41 coil.
* Tips & Hints.
* Questions and Answer Technical Session

We hope to see you there.

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm
```

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

```
The Saturday 40 meter net had 20 stations
checking in under good band conditions. There
were 5 new stations checking in, W3SSF, N9JR,
KB2TOZ, VE3ZBM, and N3JDR. We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
3 running TS-820(x)
9 running TS-830S

I was running my TS-940s with an L4B amplifier.

The Sunday 20 meter net was run by Jimmy,
WB2KNR. He had 30 check-in under good band
conditions. There were 4 new check-ins, WB0CJB,
KC9WKY, N8VKX, and KD0VEP. We had the following number of radios.
```

3 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
5 running TS-830S

Jimmy was running his TS-520.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85
March 2014, Saturday□s net total = 20, Sunday□s total = 16 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

Last suggestion:

If you are missing the VCO signal at the RF board make sure that the VCO coax cable connector socket is soldered at each end. Sometimes you can confirm this is the problem by simply wiggling the connector at each end of the cable and see the display come and go.

Easy to pull the socket loose or break the solder connection when you pull this cable to remove the board for cleaning. When you pull the cable good idea to apply a small amount of deoxit to the mating surfaces of the plug and socket.

I am not sure I understand what your operational issue is. I believe it is blanked display and if so first thing I would measure is VCO signal at the RF board and at the PLL board.

47964. Really strange 820 issue...

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-04 18:40:00 UTC
From: <hanson1448@...>
Topic: 47964 Message: 47964

I have a really nice 820 with a very strange issue. The radio will work 100% with great receive/full output...and intermediately, (abt every 2 hours) just quit...everything goes dead ...just static thru the speaker, and the VFO red marker light showing on the panel. Exactly the same symptoms as if u pulled the VFO shorting plug. Now...if I remove the plug, and soak it in alcohol, and reinsert it, everything comes back to life for another two hours or so. I have tried several vfo plugs, plus a shorting wire.Also, if I substitute Deoxit 5 for rubbing alcohol, it has no effect! Only soaking the vfo plug or shorting wire in alcohol will bring the radio back.

Any ideas appreciated.

Hmmm.

Okay -- we know that DeoxIT is not conductive, so would do nothing to "bridge the gap" in an ill-fitting jack/socket mating. Alcohol MAY act as a conductor, depending upon its type and particular makeup. So, it's possible that the alcohol is is somehow filling the void in the jack -- until it evaporates. DeoxIT could perhaps help clean the jack, if corroded, but could not act as a conductive substance between the plug pins and individual jack socket(s) that has/have been damaged and gotten too loose to fit the plug.

Maybe.

47968. TS-830S - PA Unit Arcing Band Switch

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-04 21:45:10 UTC
From: Robert Allen
Topic: 47968 Message: 47968

Hello to All:
I have a TS-830S which I am the original owner. About two months ago, I tried to put it back on the air - not used in the xmit position for many years.

When I put it in TUNE position I did have RF output. When put in CW position, there was considerable arcing in the PA Unit band switch -looking from the end into the PA unit with fan removed - lower left and the first wafer - freq on 14 MC.

I then replaced HV caps , L1,C7 and C8. The band switch is still arcing? Not a too complicated circuit?

Any thoughts or suggestions as to what is going on ?
Thanks for any assistance
Bob W1ZX

Is the band switch dirty? If there's a lot of black muck that collected on the wafer contacts, it could be the problem.

Ok---I was hoping the clues would lead you to the schematic with emphasis on the Driver tube cathode circuit.

1. Big difference = 530 board has no provision for RF negative feedback which you want to retain on the 830. However, can easily move the components over from the 830 board to the 530 board. The 530 board has the solder pads and traces for this. Need to remove a small jumper (looks like a miniature resistor) in the driver tube cathode circuit and install rf choke and the white lead wire. If you study the driver tube cathode circuit of the 830 you will see what you have to do on the 530 board to configure same as 830.

2. Medium difference = 530 board has no provision for 10 meter rf output for Transverter operation. Need to move over a molex connector and cap and resistor. Only medium if transverter operation is important to you. Otherwise no need to do anything.

3. Little difference = 530 board has a little different RIF mixer FET bias adjustment. It has no VR-1 trim pot to adjust the drain current balance by adjusting the bias resistance in the source leads. This is an enhancement in the 830 board to reduce any strong local broadcast band (BCB) leak thru in the 8.830 RIF. You should not notice any difference unless live in urban area with many high power BCB stations.

These are differences that I am aware of. May be some other small differences. If I was installing a 530 RF board into a 830 only thing I would concern myself with is transferring the components to allow RF negative feedback to function. In addition to improving SSB linearity this circuit also limits the rf voltage swing across the plate loading capacitor in presence of very high VSWR that would be encountered in an open at the SO-239 (open coax jumper etc).

What I am telling you is what I believe from circuit analysis and not what I know from experience as I have never made the swap.

Craig:

I forgot to mention that the TS830 driver stage is neutralized and the TS530 is not so you will also need to move C75 cap from the foil side of the TS830 RF board and install it on the TS530 RF board before you install it in your TS830.

Driver stage RF negative feedback and neutralization components should be swapped from the 830 RF board to the 530 board.

Terrific info, Terry. I have just acquired a spare 530 board and thought I'd give it a go. A cursory glance showed little difference with perfectly "do-able" mods to be made.

I will definitely install the components to provide RF negative feedback. I may also do the RIF mixer enhancement since I live precisely one mile from a 50 KW, clear channel AM BCB station. I must say, however, that despite its proximity, this station does not seem to annoy either my 530 or 830. These Kenwoods, incidentally, are the ONLY radios I have ever owned that did not require a band stop filter to cope with the nearby broadcaster.

Thanks again!

When you say low drive do you mean low ALC indication or low rf output power or both ?

Go to RF board Molex conn RF-3 and measure RF-1 Pin 3 should be approx 3.3vdc. Then measure Pin 6 ALC should be approx 2.6vdc or so with a 11 meg VTVM or 10 meg DMM.

Go to IF board Molex conn IF-3 and measure AGL Pin 6 should be approx 2.6vdc (same as what you measured at RF board). This is the ALC bus voltage switched by the aux relay that you just cleaned and swapped.

If ALC bus voltage is missing at IF board and you have a dc bench supply or couple or 1.5vdc flashlite batteries connect 3.0vdc to AGL and see if TX comes alive. 3vdc source should produce TIF amp output and drive the TX Mixer. With low Z 3vdc applied wont get any ALC indication but should get full RF output.

Bob,

Best to open and discharge HV system then remove PA cover, you could have a critter or a build up of dust and moisture. Give the PA a good clean out and see if you can locate any carbon marks and work from there

From: <dcurry@...>
Topic: 47978 Message: 47978

Hello, again.

On my 'other' TS-520, I would like to work digital modes. While I was in the Army, I was a 'Rat Rig' operator, running encrypted text and phone through a rig pushing 10KW (How i wish I had THAT setup, for the hobby!).

I have been successful with running the audio out of the radio, from the external speaker port to read the messages sent. I have successfully made one QSO by holding the mic near the speakers of the laptop when transmitting.

What is the best (bang for buck) interface to automate (and silence) this connection?

Thanks

Daniel/KK4SWX

47979. TS-520 does not xmit

On 03/04/2014 09:31 PM, dcurry@... wrote:
> What is the best (bang for buck) interface to automate (and silence) this connection?

Well, Daniel, the "bang" I got from a simple phone plug going from the phone patch out plug on the back of my 520SE to the microphone input jack on my Linux laptop, and a free open-source Morse and PSK tone decoder was pretty substantial.... Hand-keyed Morse all the way up to machine-generated. All the tone-based packet modes, too.

It's only 8 ohms out, so a matching transformer might be a good idea, depending on whether your computer sound card can handle input at that level. I had to attenuate almost to the lowest setting with the software volume controls in the operating system control panel, but it worked right out of the starting gate once I trimmed the signal levels down low enough.

The first program I tried had problems with the SLOW end of CW. Speeds below about 15 wpm weren't reliably decoded. Above that, though, it was flawless when the signal was good enough.

With a relay or an electronic switch in between the laptop and the rig to key it, I could add another short cable and -send- morse, too, with the same software. Probably cost me about ten bucks to build the interface, more or less, depending on how hard I scavenged the junkbox at home for the bits. A telephone modem (like we used to use for internet access) will output all the proper tones, if your sound card won't deal with them by itself. Most sound cards do, these days....

All kinds of possibilities abound. Even with old hybrid rigs, all you need do is bear in mind the signal levels you need for inputs, and what you have available as outputs (and where), and buffer or moderate between them. Audio signal transformers can be cabbaged out of old AM radios, and the like, for instance. Or you can buy them new if you're not limited in funds.

Here's a web site, even has the Kenwood 8-pin mike connections for the example schematic:

http://wa8lmf.net/ham/tonekeyer.htm

There are loads of other sites that have similar information. Have fun, you'll be amazed at what you can get these old machines to do, with a computer to help out. (I'm also planning on interfacing a "Midnight Design Solutions" Micro-908 antenna analyzer (N2APB is the designer) with the digital signal processing board to my 520SE as an external VFO as well as all the packet and other data modes. With that little marvel I won't even need the computer, it does it all by itself. But I -can-

put the computer on there as well for even more features. If you can find a Micro-908, GRAB IT. They're fantastic!

First and most simple, check the screen voltage slide switch on the back corner of the radio. Make sure its on.

I found a couple of the ground wire wrapped terminals on the circuit board in 530 soldered. Did any of these wire wrapped post come soldered from the factory or is it an indication of a repair?

Thanks Brian KB4MNG

Welcome Daniel to the wonderful world of ham radio!

Make sure the “SG” (screen grid) on the back of the rig is ON. This switch is used when neutralizing a new set of finals too. The “H SW” in the front also has to be ON. (heater).

There could be many reasons for no TX. Some include faulty 6146 output tubes or even a faulty 12BY7 tube, the 82pf 3Kv capacitor in the final could be burnt out, the TX relay, etc. If No ACC there could be no plate current and maybe a bad transistor in the IF unit x48-1060, Q2 I think.

Looking at note I see also that R70 and/or R71 in the RF unit could be bad or even R5 in the rectifier unit.

So many possibilities.. have you tried K4EAA’s tune-up procedures?

<http://www.k4eaa.com/tune-up.htm> http://www.k4eaa.com/tune-up.htm

Subject: [TS-520_820_530_830] TS-520 does not xmit

Greetings, all!

I'm a new Ham, though I've been around the hobby most all my life, due to my father being a Ham.
I have a TS-520 (no S or SE) that does not xmit, though it does receive.
Where do I start the troubleshooting on this, without an O'scope?

Thanks

Daniel/KK4SWX

The main thing you want to do is to break the ground between the radio and the computer.

I run RTTY on my Benton Harbor S-Line Twins. I rewired a Heathkit phone patch just as straight transformers. It works very well.

> What is the best (bang for buck) interface to automate (and silence) this connection?

Well, Daniel, the "bang" I got from a simple phone plug going from the phone patch out plug on the back of my 520SE to the microphone input jack on my Linux laptop, and a free open-source Morse and PSK tone decoder was pretty substantial.... Hand-keyed Morse all the way up to machine-generated. All the tone-based packet modes, too.

It's only 8 ohms out, so a matching transformer might be a good idea, depending on whether your computer sound card can handle input at that level. I had to attenuate almost to the lowest setting with the software volume controls in the operating system control panel, but it worked right out of the starting gate once I trimmed the signal levels down low enough.

The first program I tried had problems with the SLOW end of CW. Speeds below about 15 wpm weren't reliably decoded. Above that, though, it was flawless when the signal was good enough.

With a relay or an electronic switch in between the laptop and the rig to key it, I could add another short cable and -send- morse, too, with the same software. Probably cost me about ten bucks to build the interface, more or less, depending on how hard I scavenged the junkbox at home for the bits. A telephone modem (like we used to use for internet access) will output all the proper tones, if your sound card won't deal with them by itself. Most sound cards do, these days....

All kinds of possibilities abound. Even with old hybrid rigs, all you need do is bear in mind the signal levels you need for inputs, and what you have available as outputs (and where), and buffer or moderate between them. Audio signal transformers can be cabbaged out of old AM

radios, and the like, for instance. Or you can buy them new if you're not limited in funds.

Here's a web site, even has the Kenwood 8-pin mike connections for the example schematic:

http://wa8lmf.net/ham/tonekeyer.htm

There are loads of other sites that have similar information. Have fun, you'll be amazed at what you can get these old machines to do, with a computer to help out. (I'm also planning on interfacing a "Midnight Design Solutions" Micro-908 antenna analyzer (N2APB is the designer) with the digital signal processing board to my 520SE as an external VFO as well as all the packet and other data modes. With that little marvel I won't even need the computer, it does it all by itself. But I -can- put the computer on there as well for even more features. If you can find a Micro-908, GRAB IT. They're fantastic!

Terry,
Yeah, I have a good VFO signal to the PLL board as indicated on my O-scope.
However, I got distracted on another radio that I just picked up, and
put the 530 aside for a few days.
Thanks for everything, Terry.
Best regards

Yes and there are plenty of websites that show how to build a "simple" sound card interface for CW, PSK, RTTY, and other so called "digital modes".

A simple sound card interface can be used for CW, PSK, RTTY, and other digital modes. The transceiver can be keyed (CW mode) using a simple transistor or opto isolator keying circuit, very easy to add to a sound card interface.

Connections to the radio and the computer's sound card can be accomplished using simple audio shielded cables. You don't need to spend a lot of money on expensive shielded cables, you won't notice any difference if you use $10 shielded cables verses $2 shielded cables, or you can make them yourself or use/buy the cheap ones found in the DVR/VCR box or at Walmart or Radio Shack.

Try using your favorite search engine to search for and find simple sound card interface circuits you can build that won't cost you an arm and a leg, most likely can be built for less than $15!!

If building a simple sound card interface is not your cup of tea then you can buy one pre-built from MFJ, SignaLink, or Rig Blaster. They typically come with instructions that you SHOULD/MUST READ before attempting to connect and operate the interface, as well as the necessary cables to make the connections between your radio and computer's sound card.

Bob,

Kenwood made the PC-1 (4 pin mic) and the PC-1A (8 pin mic). They are identical except for the mic connectors. A web search will turn up the pictures, manuals, and schematics.

OK loss of VFO input is common problem and easy to have happen after removing the PLL board or cycling the molex connectors to the board.

When or if you need to come back again maybe refresh all of us as to the problem and how it manifests itself. These problems all start to run together. We all like to hear the fix and learn from it.

Fortunately the TS530 and TS830 PLL boards are pretty reliable and previous owners dont often apply golden screwdriver to them. Unlike the RF and IF boards which see lots of "tweaking".

Yes they did Bob, it's the "PC-1A". The schematic indicates it can be easily used as a sound card interface with a few changes.

http://www.kg6haf.com/downloads/PC1A_Phone_Patch.pdf

There's a Kenwood PC-1A being sold on eBay right now with a Buy It Now price of $39.99, "Free standard shipping".

http://www.ebay.com/itm/like/161196993756?lpid=82

Thanks Ken for the update on the PC-1 and PC-1A. It wouldn't require
much work to modify the PC-1 or PC-1A to be used as a sound card interface.

No KW factory did not solder any of the wire wraps.

Wire wrap is a very old and reliable termination method. If done correctly never a reason to solder. The soft copper actually deforms against the sharp edges of the hardened post and oxide coating is broken and very high contact pressure is developed and typical contact resistance is < 1.0 milliohms. The wraps are actually gas tight so connections are good for 40 plus years. Navy avionics did a lot of testing on this type of termination. Can find some interesting white papers on this subject.

When you remove a wire wrap must cut off all the old wire from the lead and not attempt to re-use it in any manner as it has work hardened. You can strip back and rewrap with proper size hand tool available from Jonard and Cooper and others, but I just file the post to brite metal and make couple of wraps near top and tack solder the lead back on. .

I just bought it!

But I will destroy is since phone patches are seldom used anymore.

I have a TS-520 which does not have a phone patch interface. But if I remember correctly the TS-520S does have a phone patch interface.

I will modify my TS-520 to add the phone patch interface. Maybe a DG-5 interface also.

Right now I am working on a 2M converter similar to the Elcraft 2M converter for use with my TS-520.

Â
Yes and there are plenty of websites that show how to build a "simple" sound card interface for CW, PSK, RTTY, and other so called "digital modes".

A simple sound card interface can be used for CW, PSK, RTTY, and other digital modes. The transceiver can be keyed (CW mode) using a simple transistor or opto isolator keying circuit, very easy to add to a sound card interface.

Connections to the radio and the computer's sound card can be accomplished using simple audio shielded cables. You don't need to spend a lot of money on expensive shielded cables, you won't notice any difference if you use $10 shielded cables verses $2 shielded cables, or you can make them yourself or use/buy the cheap ones found in the DVR/VCR box or at Walmart or Radio Shack.

Try using your favorite search engine to search for and find simple sound card interface circuits you can build that won't cost you an arm and a leg, most likely can be built for less than $15!!

If building a simple sound card interface is not your cup of tea then you can buy one pre-built from MFJ, SignaLink, or Rig Blaster. They typically come with instructions that you SHOULD/MUST READ before attempting to connect and operate the interface, as well as the necessary cables to make the connections between your radio and computer's sound card.

Well, Daniel, the "bang" I got from a simple phone plug going from the phone patch out plug on the back of my 520SE to the microphone input jack on my Linux laptop, and a free open-source Morse and PSK tone decoder was pretty substantial.... Hand-keyed Morse all the way up to machine-generated. All the tone-based packet modes, too.

It's only 8 ohms out, so a matching transformer might be a good idea, depending on whether your computer sound card can handle input at that level. I had to attenuate almost to the lowest setting with the software volume controls in the operating system control panel, but it worked right out of the starting gate once I trimmed the signal levels down low enough.

The first program I tried had problems with the SLOW end of CW. Speeds below about 15 wpm weren't reliably decoded. Above that, though, it was flawless when the signal was good enough.

With a relay or an electronic switch in between the laptop and the rig to key it, I could add another short cable and -send- morse, too, with the same software. Probably cost me about ten bucks to build the interface, more or less, depending on how hard I scavenged the junkbox at home for the bits. A telephone modem (like we used to use for internet access) will output all the proper tones, if your sound card won't deal with them by itself. Most sound cards do, these days....

All kinds of possibilities abound. Even with old hybrid rigs, all you need do is bear in mind the signal levels you need for inputs, and what you have available as outputs (and where), and buffer or moderate between them. Audio signal transformers can be cabbaged out of old AM radios, and the like, for instance. Or you can buy them new if you're not limited in funds.

Here's a web site, even has the Kenwood 8-pin mike connections for the example schematic:

http://wa8lmf.net/ham/tonekeyer.htm

There are loads of other sites that have similar information. Have fun, you'll be amazed at what you can get these old machines to do, with a computer to help out. (I'm also planning on interfacing a "Midnight Design Solutions" Micro-908 antenna analyzer (N2APB is the designer) with the digital signal processing board to my 520SE as an external VFO as well as all the packet and other data modes. With that little marvel I won't even need the computer, it does it all by itself. But I -can- put the computer on there as well for even more features. If you can find a Micro-908, GRAB IT. "82 pf 3kv capacitor"?? If you are talking about RF drive inter-stage coupling cap, this is a Kenwood Hybrid and not a Yaesu FT-101.
R70/R71 are driver tube screen grid divider resistors. They very seldom fail. When they do it is usually due to radio having been "hot rodded" by CB owner.

Q2 is the TIF amp and very rare for it to fail.

At this point we could make a list of 100 possible failures. There is a difference between "eperiential based" troubleshooting and "easter egging/shot-gunning" and just plain guessing. Nothing wrong with model specific "experiential based" approach but long way from sharing those things.

The "operator error" stuff you initially pointed out is very good place to start. Once we find out the SG switch and Heaters are on can then ask some more clarifying questions.

Actually the PHONE PATCH IN and PHONE PATCH OUT sockets are on the TS-520S and TS-520SE, not the TS-520.

The PHONE PATCH IN connects to the GENERATOR UNIT's "PCH" terminal then through R10 (100K) to the negative terminal of C14 (1ufd 25VDC) capacitor. All this does is bypass resistors R7, R8 that connect to pin 1 of the microphone socket. The resistive voltage divider of R9 (10K) and R10 (100K) simply reduces the audio level that's applied to the base of Q3 through C14 on the GENERATOR UNIT board.

The PHONE PATCH OUT connects to the AF UNIT's "SP" terminal, same as the speaker.

There's no isolation on either PHONE PATCH IN/OUT sockets.

Ken,

Thanks for the info, but I do not understand what a 'phone patch' will do for me?

I've been looking for a way to actually key the radio from the computer. What what I have seen, so far, that usually requires the serial port on the computer to toggle a relay of some kind, which then keys up the radio for the soundcard output to be fed into the mic audio.

Or am I mis-understanding how this is supposed to work?

Bob,

I have a DG-5 I would like to add to either of these TS-520's I have. I have been told the DK-5 or DK-520 kits very difficult to come by, these days. I've also been told that same mod/kit can be used for panoramic views of the band. A very helpful addendum to anyone seeking digital signals that may be too low to be heard by the human ear.

If you come across a source for these, please let me know.

Thanks,

Daniel

You can use the phone patch to make the transformer coupled interface. But it does require rewiring the phone patch.

With my Benton Harbor S-Line Twins the transmitter is keyed by the VOX. I am hoping this will work also with the TS-520.

Daniel,

I have the documentation on the mod kit for the TS-520/DG-5 interface. I have been thinking about making PCB for this mod.

But I do not have a DG-5. I have been thinking about a DG-5 clone. I thought someone was trying to do this but I have not seen it.

Yes they did Bob, it's the "PC-1A". The schematic indicates it can be easily used as a sound card interface with a few changes.

http://www.kg6haf.com/downloads/PC1A_Phone_Patch.pdf

There's a Kenwood PC-1A being sold on eBay right now with a Buy It Now price of $39.99, "Free standard shipping".

http://www.ebay.com/itm/like/161196993756?lpid=82

Yes and there are plenty of websites that show how to build a "simple" sound card interface for CW, PSK, RTTY, and other so called "digital modes".

A simple sound card interface can be used for CW, PSK, RTTY, and other digital modes. The transceiver can be keyed (CW mode) using a simple transistor or opto isolator keying circuit, very easy to add to a sound card interface.

Connections to the radio and the computer's sound card can be accomplished using simple audio shielded cables. You don't need to spend a lot of money on expensive shielded cables,

you won't notice any difference if you use $10 shielded cables verses $2 shielded cables, or you can make them yourself or use/buy the cheap ones found in the DVR/VCR box or at Walmart or Radio Shack.

Try using your favorite search engine to search for and find simple sound card interface circuits you can build that won't cost you an arm and a leg, most likely can be built for less than $15!!

If building a simple sound card interface is not your cup of tea then you can buy one pre-built from MFJ, SignaLink, or Rig Blaster. They typically come with instructions that you SHOULD/MUST READ before attempting to connect and operate the interface, as well as the necessary cables to make the connections between your radio and computer's sound card.

> What is the best (bang for buck) interface to automate (and silence) this connection?

Well, Daniel, the "bang" I got from a simple phone plug going from the phone patch out plug on the back of my 520SE to the microphone input jack on my Linux laptop, and a free open-source Morse and PSK tone decoder was pretty substantial.... Hand-keyed Morse all the way up to machine-generated. All the tone-based packet modes, too.

It's only 8 ohms out, so a matching transformer might be a good idea, depending on whether your computer sound card can handle input at that level. I had to attenuate almost to the lowest setting with the software volume controls in the operating system control panel, but it worked right out of the starting gate once I trimmed the signal levels down low enough.

The first program I tried had problems with the SLOW end of CW. Speeds below about 15 wpm weren't reliably decoded. Above that, though, it was flawless when the signal was good enough.

With a relay or an electronic switch in between the laptop and the rig to key it, I could add another short cable and -send- morse, too, with the same software. Probably cost me about ten bucks to build the interface, more or less, depending on how hard I scavenged the junkbox at home for the bits. A telephone modem (like we used to use for internet access) will output all the proper tones, if your sound card won't deal with them by itself. Most sound cards do, these days....

All kinds of possibilities abound. Even with old hybrid rigs, all you need do is bear in mind the signal levels you need for inputs, and what you have available as outputs (and where), and buffer or moderate between them. Audio signal transformers can be cabbaged out of old AM radios, and the like, for instance. Or you can buy them new if you're not limited in funds.

Here's a web site, even has the Kenwood 8-pin mike connections for the example schematic:

http://wa8lmf.net/ham/tonekeyer.htm

There are loads of other sites that have similar information. Have fun, you'll be amazed at what you can get these old machines to do, with a computer to help out. (I'm also planning on interfacing a "Midnight Design Solutions" Micro-908 antenna analyzer (N2APB is the designer) with the digital signal processing board to my 520SE as an external VFO as well as all the packet and other data modes. With that little marvel I won't even need the computer, it does it all by itself. But I -can- put the computer on there as well for even more features. If you can find a Micro-908, GRAB IT. They're fantastic!

With a relay or an electronic switch in between the laptop and the rig to key it, I could add another short cable and -send- morse, too, with the same software. Probably cost me about ten bucks to build the interface, more or less, depending on how hard I scavenged the junkbox at home for the bits. A telephone modem (like we used to use for internet access) will output all the proper tones, if your sound card won't deal with them by itself. Most sound cards do, these days....

All kinds of possibilities abound. Even with old hybrid rigs, all you need do is bear in mind the signal levels you need for inputs, and what you have available as outputs (and where), and buffer or moderate between them. Audio signal transformers can be cabbaged out of old AM radios, and the like, for instance. Or you can buy them new if you're not limited in funds.

Here's a web site, even has the Kenwood 8-pin mike connections for the example schematic:

http://wa8lmf.net/ham/tonekeyer.htm

There are loads of other sites that have similar information. Have fun, you'll be amazed at what you can get these old machines to do, with a computer to help out. (I'm also planning on interfacing a "Midnight Design Solutions" Micro-908 antenna analyzer (N2APB is the designer) with the digital signal processing board to my 520SE as an external VFO as well as all the packet and other data modes. With that little marvel I won't even need the computer, it does it all by itself. But I -can- put the computer on there as well for even more features. If you can find a Micro-908, GRAB IT. They're fantastic!

48008. DDS VFO for 530 or 830

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-06 03:41:17 UTC
From: <cocobean64@...>
Topic: 48008 Message: 48008

Been working on this project for a while now, nearing completion. A couple of pictures can be found under the "Photos" heading. Look for the album DDS VFO for 530 or 830.

The idea came to me that I wanted to use NaP3 with my LP-Pan2 pan-adapter, on my Kenwood 530 and 830.
Since there is no "pc connection" on the rigs, this was not possible.

Now it is. The unit will plug into the existing " external vfo" connector on the back of the set. Rit, xit, split functions, vfo selection, a to b to a transfer all possible with the touch screen and it functions seamlessly with Nap3.
Its based on the Arduino Due microprocessor, uses two optical encoders (for rit and vfo functions), AD 9850 DDS oscilator to put out a frequency of 5.3 to 6.1Mhz (mimicking the OEM VFO).
Pertinent info (last vfo a / b frequencies and rit/xit) are stored on as SD card, and read in upon power up.

A second (smaller) Arduino microprocessor will be installed in the radio. It will monitor band switch, mode switch and Tx/Rx status. This info will be sent via serial (2 wire) communication back to the main unit for processing.

Not only will this work for Kenwood hybrids, but I think any other rig that has a mechanical vfo. You get the benefit of a rock-solid signal (no drift) and a useful panadapter.

Yes and there are plenty of websites that show how to build a "simple" sound card interface for CW, PSK, RTTY, and other so called "digital modes".

A simple sound card interface can be used for CW, PSK, RTTY, and other digital modes. The transceiver can be keyed (CW mode) using a simple transistor or opto isolator keying circuit, very easy to add to a sound card interface.

Connections to the radio and the computer's sound card can be accomplished using simple audio shielded cables. You don't need to spend a lot of money on expensive shielded cables, you won't notice any difference if you use $10 shielded cables verses $2 shielded cables, or you can make them yourself or use/buy the cheap ones found in the DVR/VCR box or at Walmart or Radio Shack.

Try using your favorite search engine to search for and find simple sound card interface circuits you can build that won't cost you an arm and a leg, most likely can be built for less than $15!!

If building a simple sound card interface is not your cup of tea then you can buy one pre-built from MFJ, SignaLink, or Rig Blaster. They typically come with instructions that you SHOULD/MUST READ before attempting to connect and operate the interface, as well as the necessary cables to make the connections between your radio and computer's sound card.

Well, Daniel, the "bang" I got from a simple phone plug going from the phone patch out plug on the back of my 520SE to the microphone input jack on my Linux laptop, and a free open-source Morse and PSK tone decoder was pretty substantial.... Hand-keyed Morse all the way up to machine-generated. All the tone-based packet modes, too.

It's only 8 ohms out, so a matching transformer might be a good idea, depending on whether your computer sound card can handle input at that level. I had to attenuate almost to the lowest setting with the software volume controls in the operating system control panel, but it worked right out of the starting gate once I trimmed the signal levels down low enough.

The first program I tried had problems with the SLOW end of CW. Speeds below about 15 wpm weren't reliably decoded. Above that, though, it was flawless when the signal was good enough.

With a relay or an electronic switch in between the laptop and the rig to key it, I could add another short cable and -send- morse, too, with the same software. Probably cost me about ten bucks to build the interface, more or less, depending on how hard I scavenged the junkbox at home for the bits. "You get the benefit of a rock-solid signal (no drift) and a useful panadapter."
This statement is a little confusing to me, your new digital VFO and the LP-Pan (panadapter hardware) are independent of each other when connected to a Kenwood hybrid, correct? Then I assume you use a PC program like "PowerSDR/IF" to combine both remote VFO (or frequency control)....AND.....a panadapter display (looking at the IF1 output of the hybrid's IF spectrum, on the back panel), correct?
Okay, I just wanted to help clear that up

Bart, Congratulations on creating and developing what appears to be the answer to a lot of 530 and 830 owners' dreams, prayers, chants, wishful thinking, wistful thinking, etc., etc. It's difficult to stop the salivation your images in the file area stimulated.
I will echo a question already made: When and where can we sign up for a kit? Not kidding! :-)
Are you thinking about taking your development to that level? Or are you more inclined to provide the block diagrams, schematics, and parts list to those interested and coach us? Or?
I gotta go this direction also, I love my 830S and this type of enhancement will extend it's useful life for a long time.
Thanks for sharing and can't wait to see and hear more.

Hi group,
After a bit of experimenting with various ideas, I have wrapped a thin bit of card around the mike element, I cut a circle to cover the top of the element and used a hole-punch to punch one hole through that. A bit of sheep's wool (lots of that around here!) on top of that got rid of any "popping" noises. According to a friend, it now sounds "natural". He was using a rig with recording facilities, and played it back to me at each modification. All happy now!
Cheers,
John

48016. Kenwood 820 VFO

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-07 03:12:08 UTC
From: Wayne Schrubbe
Topic: 48016 Message: 48016

Hi Guys,
I am back with a nother question! I am running a TS520s, with the DG-5 display,
and useing a Astatic DN-HZ microphone head. I love it! Everything works great but the noise blanker (I can live with that!).
I was given a Kenwood 820 vfo, and I was woundering if I can use it on my TS520s? If I can, does anyone know the wiring for that? I took the cover off it and it looks like brand new inside! But the vfo knob is cracked and is useless. I am thinking an MFJ replacement will do fine. The vfo turns very hard. Is there some way I can free that up (oil/greese maybe)? or do I have to take it apart to overhall it? I have never done anything like that so it will be all new to me. Any tips or how to's would be greatly apperciated. If I do take this apart, I will need all the help I can get.

PS. in my last letter, I asked about a DC to DC converter. Well I got one! Both the exturnal converter and the power transformer (from a ts 520) for $50 buck!! It looks to be in good shape.
So did I get ripped off? Tell me what you think!...
Thanks for the help!

Hello Jan,

Yes they are independent from each other.
Panadapter is connected to the rear IF output of the radio, and sound input of the PC.
The DDS VFO is also connected to the PC (via USB) and communicates (via the pc) with in my case NaP3.

To answer the question others had asked about kits....
As to kit availability, that's perhaps for the near future. First I need to get this one finished. It's a bit of a slow process as I work on it only when home. (my job is field service).
As I progress I will keep posting updates and pictures. If anyone has specific questions feel free to e-mail me at cocobean64@gmail.com. I will answer when time permits.

Hi All,

Good job on the DDS VFO. However, the 530s does not have an IF 1 or 2 port for the pan display. I have installed both on one of my 530's, and it goes 6dB deaf and creates other slight problems on the IF board. Now this can be over come with some minor buffering which will preventing the IF ports from dragging the sensitivity down. So with the PAN SDR adaptor kit, are you taking it straight off the IF board?

Regards,

Dave

48021. Legacy Alignment Instructions Manuals

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-07 13:49:37 UTC
From: Mark Gilger
Topic: 48021 Message: 48021

One new item that's been added, thanks to the great effort from Dick, W0NTA are Alignment Instruction manuals. These are appropriate pages pulled out of the service manual to make a condensed, easy to handle manual, verses the bulkier service manuals.

The following are available on http://wb4hfn.com/KENWOOD/KenwoodHomePage.htm and some at Dicks site : http://w0nta.com/

TS-520
TS-530S
TS-820S
R-820
TS-830S
TS-940S

More of these alignment manuals will be coming as time permits.

I know, the TS-940s is not a hybrid, but ha, it's my site. Since I own 3 of these I figured why not.....

Thanks,
Mark, WB0IQK

48022. Re: [TS-520_820_530_830] Kenwood 820 VFO

From: Mike W5RKL
Topic: 48016 Message: 48022

Wayne,

Yes, the VFO-820 will work with the TS-520 "PLug and Play". The connecting cable is a straight through, pin to pin (1 to 1, 2 to 2, 3 to 3 etc), no cross overs and no jumpers in the cable. If you do not have the VFO connecting cable then you will either have to find one on the web or build one yourself. I have no source for the 9 pin male plugs, 2 are required one on each end.

You say the Noise Blanker doesn't work. How did you come to that conclusion? Are you aware the Noise Blanker only works on "pulse" type noise such as power line arcing and ignition noise? Quite often people think the noise blanker in the KW hybrids will eliminate ALL noise but that's not true. The operator's manual discusses that the noise blanker only works on pulse type noise. If the noise you are trying to eliminate is not a pulse type noise then the 520 noise blanker will have no affect on the noise.

You said you purchased the DS-1A along with a power transformer and wonder if you got ripped off. "IF" the DS-1A is bad, say one of the transistors is bad, then it will cost you approximately $100 or more to replace the transistors. The price depends on where you can find the NTE-28 or 2N4049 transistors. If only one transistor is bad then you should replace both transistors. The 2N4049 or NTE-28 transistors are not cheap. Also, if the power transformer is bad, say only one winding is bad (shorted), then the transformer will have to be rewound before you can use it. You cannot use the transformer by simply not using a shorted winding. The transformer will need to be rewound and that can be expensive. For example, TRS (Transformer Rewinding Service) will rewind a bad TS-520S power transformer for $188 plus 2 x shipping. How do you tell if the transformer is bad? There are a couple of ways that do not require applying power. First, smell the transformer. If it smells like burnt tar or burnt grease then one or more windings have overheated and have shorted. Second, you can measure the DC resistance of each winding. I don't have the individual resistance values for each winding, maybe another member has it. Don't guess! No you cannot leave the bad winding disconnected and use the other windings, transformers do not work like that when a winding is shorted.

As for the VFO being hard to turn, sounds like the bearing grease has become dried out and hard. Clean the bearings grease should help free up the VFO shaft making it easier to rotate.

The nine pin connector can be made by using two nine pin tube sockets.

You remove the female pins from the sockets and insert brass wire from a hobby shop (K&S brass wire).

I use a socket with the female pins as a jig to assemble these connectors. I use epoxy on the back side of the connector to retain the new pins in the sockets.

Hi Dave,
I also added an IF port to my 530 and it apparently works without
loading down the IF signal. I'm using a Softrock Ensemble II. I followed
the same wiring as the 830. Maybe you did too?
SDR panadapter for the Kenwood hybrid is one of my lectures at the
Dayton Hamvention on Sunday.

Most of Gordon's stuff has now been posted on my web site. If anyone finds something that's missing and feels it should be included, you can email me the needed information and I'll see that it gets posted.

I should also mention that I did not include all of the stuff on his web site, as there was some that was not Hybrid Legacy related. As time goes on I might be getting some of the non-hybrid stuff up there, but for now the focus is on the Hybrid stuff.

Thanks,
Mark, WB0IQK

I'm on a quest to find out who held my vanity callsign, W5CNW, and it's predecessor, 5CNW (before the late 1920's there was no prefix in the US) before I got it in late 2012.

Does anyone know of archived callbooks online? Or does anyone here have old ones they could look it up in? The only callbook I have is from 1916, and they had not yet gotten up to 5CNW then.

Thank y'all!

48031. D-104 and Kenwood TS-520 - wiring (again)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-07 20:24:34 UTC
From: <lpleach@...>
Topic: 48031 Message: 48031

I've searched the Internet and have not found quite the information that I need to get my newly acquired Astatic D-104 (Tug8 4-pin, unamplified) working properly. I'm new to this group and new to Ham radio. just got my General ticket a few weeks ago and am eager to get on the air!
My D104 keys up but that's all I get out of it.
I've checked the schematic and it appears to be wired in it's original configuration, but it doesn't include clear instructions on how the cable is to be wired.
Here's what I have:

Cable Connected to Mic wires
braided wire tab 1 black wire
shielded tab 2 white/green and green
red tab 3 yellow
black - snipped off/not connected

The white/green and yellow wires are the PTT switch, which is a SPST and the switch is grounded.This is rather confusing as the rig is supposed to have pin 2 and 3 as the switch and the other 2 pins for the mic. As it is now, only 3 pins are actually connected. I'm stumped.

Larry,

Do you have the schematic for that specific stand? I attached a diagram of what I believe you have. It will be stripped by the reflector so I copied your direct address so you should get it.

The diagram I sent you does not have the same cable you described but that is not important. I will describe what I have done to similar stands. If I have the correct diagram for your stand you will notice that one side of the mic is grounded. The mic for a TS-520 should not have either side of the mic grounded (to avoid hum) so you will need to disconnect the grounded side. You will also notice that the mic is normally short-circuited (grounded) unless the PTT bar is squeezed. That prevents using VOX.

The following rewiring instructions will permit VOX and isolate the mic from ground as well as the PTT circuit. Since there is only one SPDT (you say yours is SPST?) switch I remove all of the wires so I have a clean work area and to reduce confusion.

Rewire the base:
1. Connect one side of the mic element directly to the center conductor of the shielded wire.
2. Connect the other side of the mic element to the shield which must not be connected to anything else in the base.
3. Connect the BLACK wire to the center, common, terminal of the SPDTswitch.
4. Connect the RED wire to the NO (Normally Open) terminal on the SPDTswitch.

On the rig end of the cable connect the specified wires to the plug pins:
Shielded center conductor to Pin 1 of the plug (mic hi)
RED wire to Pin 2 (PTT)
Black wire to Pin 3 (PTT ground)
Shield to Pin 4 (mic lo)

Good luck and keep us advised of your progress!

Larry,

The D-104 microphones have the wiring schematic pasted on the inside of the microphone stand bottom cover. I recommend removing the microphone stand's bottom cover where you should find the microphone PTT/Microphone element schematic.

GM to all. I'm working on a friends TS-520SE. It receives and transmits just fine. The question is in the S-meter. In both TX and RX it is over-sensitive. In RX I have to use the RF ATTN button to get the needle to quit banging the right stop. In TX I have to reduce TX power to almost nothing to get the needle to come off the right stop when tuning up. The manual has no info on any adjustments and the owner said that he has not played with any adjustments. Would the Group have a suggestion on a remedy?
Thanks & 73,
Pete WW3O

Pete,

The TS-520S service manual can be used with the TS-520SE and it has the "S meter" VR1 and VR2 pots on the IF Unit board adjustments. These pots control the meter level and sensitivity in receive (S Units) AND in TX tune up displaying ALC.

You didn't say what position the meter switch is set to when tuning the transmitter and the meter pegs full scale/peg fully to the right. I suspect the meter switch was set to "ALC" since you are saying both receive S meter AND the TX meter is pegging fully to the right. If this is true then you should check the TS-520S Service manual's "S Meter" adjustment.

Topic: 4279 Message: 48038

Pete,

I forgot to say, the S meter and ALC pots on the IF Unit are "VR1" and "VR2". It's likely these pots are dirty. VR1 and VR2 on the IF Unit board are the same in the TS-520S and TS-520SE and the TS-520S S Meter adjustment in the 520S service manual can be performed in the 520SE.

The TS-520SE is very much the same radio as the TS-520S. There are some differences such as in the power supply (no DS-1A DC power capabilities and main power is either 120VAC or 240VAC power ONLY), the heater switch was eliminated and the previous HEATER switch in the TS-520S was changed to a WIDE/NARROW filter select switch in the 520SE.

on the right hand side there is a small door- open it and the first knob (from the rear side) is for RF movement on meter- may be that potentiometer is dirty- clean it rotate it back and forth many times and then adjust final settings using a dummy load and power meter with100 watts out put to needle position at 220 ma at meter while transmitting (keying the transmitter) and your are in the business !!!

48040. TS-520 VOX issue

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-08 15:04:16 UTC
From: <ccunert@...>
Topic: 48040 Message: 48040

Hey guys:
I still have my first real rig I bought in 1975, a TS-520 that still puts out a good 100 Watts nice and steady. Receives very well, but may get the front end tuned up to be sure, S meter works very well. No apparent problems with any of the features except one. To transmit SSB or CW I have to turn on the send switch only. When I move the VOX switch from manual to VOX and close the CW key or press PTT on the mic it will not transmit, but will transmit when the send is used. In other words the full break in is unavailable. I can hear the VOX relay activate and stay engaged for about 1 second, there is no sidetone for this second. There seems to be transmit power out for the 1 second. No matter where I set VOX gain, delay or anti VOX the same situation exists. Anyone have any ideas where to start?

I too, am having issues with VOX on a stock TS-520. I have to really shout to get it to transmit, using an MC-50 microphone that works wonderfully, when in manual. I have no knobs on the face of the transceiver labeled anything related to VOX, or am I missing something. Thanks.

Ken,
This looks like what I'm looking for. The only difference is that the switch defaults to the other position. No biggie.
I'm attaching a pic of the base wiring.
So here's what I have so far:

1. Connect one side of the mic element directly to the center conductor of the shielded wire.
Black wire of the mic to the center shielded wire. Check!

2. Connect the other side of the mic element to the shield which must not be connected to anything else in the base.
Green wire to shield wire. Check!

3. Connect the BLACK wire to the center, common, terminal of the SPDT switch.
Which black wire? The one from the cable? The one from the mic is already connected to the center shielded wire.

4. Connect the RED wire to the NO (Normally Open) terminal on the SPDT switch.
Red wire connected to the yellow wire. Schematic shows this as the NO side. It was already connected in the original wiring. Does it matter if it's on a tab/post or does it have to be directly connected only like the others?

48043. TS830: Delayed receive recovery after transmit

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-08 21:36:52 UTC
From: <alan_wolf69@...>
Topic: 48043 Message: 48043

I know that delayed receive recovery is a common issue in these rigs. I did the tap test on the AF board RL1 - no effect - but since I was motivated, I replaced the relay anyway. No change. What would be the next logical thing to look for - issues with the antenna relay? I hoping that the group experience can point me in a reasonable direction to look. One observation: If the transmit time is very short (few seconds), recovery is normal. If transmit time is a minute or longer, the the delayed recovery is 5+ seconds. Problem is the same on all bands all modes. There are no other issues with radio. No transmit or receive problems except for the delayed recovery. And it really is great to have a group with so much experience and knowledge. Thanks - Al K2QU.

Subject: Re: [TS-520_820_530_830] RE: DDS VFO for 530 or 830

Hi Dave,
I also added an IF port to my 530 and it apparently works without loading down the IF signal. I'm using a Softrock Ensemble II. I followed the same wiring as the 830. Maybe you did too?
SDR panadapter for the Kenwood hybrid is one of my lectures at the Dayton Hamvention on Sunday.
Jan N8CBX

fpath fpath wrote:

Hi All,

Good job on the DDS VFO. However, the 530s does not have an IF 1 or 2 port for the pan display. I have installed both on one of my 530's, and it goes 6dB deaf and creates other slight problems on the IF board. Now this can be over come with some minor buffering which will preventing the IF ports from dragging the sensitivity down. So with the PAN SDR adaptor kit, are you taking it straight off the IF board?

Regards,

Dave

Subject: [TS-520_820_530_830] RE: DDS VFO for 530 or 830

Hello Jan,

Yes they are independent from each other.
Panadapter is connected to the rear IF output of the radio, and sound input of the PC.
The DDS VFO is also connected to the PC (via USB) and communicates (via the pc) with in my

case NaP3.

To answer the question others had asked about kits....
As to kit availability, that's perhaps for the near future. First I need to get this one finished. It's a bit of a slow process as I work on it only when home. (my job is field service).
As I progress I will keep posting updates and pictures. If anyone has specific questions feel free to e-mail me at cocobean64@.... I will answer when time permits.

The problem is not the microphone or the CW sidetone. It's not the relay control circuit on the VOX Unit board either because if it were the VOX Relay control circuit then the relays would not energize when you flip the SEND switch to transmit. The PTT "and" the SEND switch are wired in "parallel", they both do the same exact thing, ground the "SS" terminal on the VOX Unit board, turning Q8, relay control transistor ON allowing the relays, both of them, to energize when the PTT button is pressed (or grounding pin 2 on the microphone socket) or flipping the SEND switch to transmit. You can see this if you look at the 520 schematic.

I mistakenly assumed the operator had taken the time and read the 520's operator's manual and knew how to set the 520 for VOX. I mean on disrespect but this is a reoccurring problem with operators who do not take the time to read the operator's manual so they understand what the individual control functions are and how to set the controls before attempting to operate their newly acquired KW hybrid.

What does the Marker signal do in that 5 second delay period? If Marker signal is attenuated as well then problem cant be dirty ANT relay. If Maker signal is not attenuated then pull the ANT relay and clean the NC contact (actually clean all contacts while you have it out). If that doesnt help try replacing the Driver Tube.

Huzzah for manual-reading... Three cheers and all that. Wish there was more of that, in general, going on.

In my tenure running the technical side (someone else did the budget and bureau-crap-cy) of a university computer support hell(sic - I lost the "p" long ago) desk, I cannot think of a single day on the front lines when I didn't use the "RTFM" term ("Read That Fine Manual" or something like that...)

Or if the ID = 10T on the other end was high enough in the hierarchy, actually having to READ manuals to them over the phone. After a short time at this job, it got so ridiculous that I started reading out publication data (copyright dates, models covered, table of contents, and so on), even the PAGE NUMBERS, to rub in the fact that I was reading this stuff out loud to someone who was obviously too dense to read for themselves. Or was incapable of reading was the other sub-text. Piled Higher and Deeper, indeed.

Yes, I occasionally got a call from the powers that annoyed, but when the position from the other end amounted to "he was being mean to me" and from my end was "I read them the WHOLE BLOODY MANUAL OUT LOUD, over the phone, FOR AN HOUR AND A HALF!! What MORE could I POSSIBLY do?" it usually meant I won the battle, when the chips were down.

If you've never sat the phones in a call center, you cannot possibly understand the sheer depths of stupidity that make up the AVERAGE call. And then you realize, as STUPID as the average caller is, half of them are by definition EVEN DUMBER THAN THAT. It really gets to you, honestly, it actually does.

Look up "Three Dead Trolls In A Baggy" on the web. They're a comedy troupe with a techie bent. Find "Wesley" (Gee, wonder why I remember his name?) doing the "Internet Help Desk" routine. Any version, the stand-up without props, or the staged version with the whole setting. THAT was my typical day. Really. I think they stole a tape from our call center and just transcribed it, down to the, "ask an 8-year-old child for her help" part.

Topic: 48040 Message: 48053

I think they're asking much too much for one, even if it has been gone through at a reputable place. I know Terry at least is a Boonton man, and I've used those meters in the past, they're good kit.

But if the Moto is as good, or at least a reasonably close second to a Boonton, what would be a -FAIR- price to pay for one? It's a model S-1340A, and it's currently in Mendon, Massachusetts, some outfit called "Tech Recovery." They tout expertise at recovering and refurbing used lab and test equipment of all sorts.

We'll assume leads/probes are included in the dicker (because, particularly at their asking price, it is a NO-GO without them), and that it includes all the other bits and parts needed to start using it out of the box. Top dollar you would expect to pay for one in working order?

They have a 30-day guarantee, and a 5-day buyer's-remorse clause for returning it for a full refund (less shipping costs, both ways). The company is not a bad outfit, it's just that I do NOT have a handle on the going rates for something as esoteric as an RF Millivolt meter.....

TIA, y'all.

Topic: 48031 Message: 48054

Larry,

Sorry for the delay but I was busy all day Saturday.

If you attached a picture to the message you sent through the reflector I did not receive it because the reflector strips attachments. When I sent the schematic to you I copied your personal e-mail address in addition to the reflector and that is why you received it. You need to copy (or send) it to my direct address, wa2lbi at gmail dot com.

Regarding step 3, connect the BLACK wire in the CABLE to the common terminal of the PTT switch.

As for step 4, if you are referring to the yellow wire that runs from the switch to the terminal on the tag strip then, yes, it is correct.

This is an extract from my original instructions to you for rewiring the base, minus the the two completed steps:
3. Connect the BLACK wire to the center, common, terminal of the SPDT switch.

4. Connect the RED wire to the NO (Normally Open) terminal on the SPDT switch.

On the rig end of the cable connect the specified wires to the plug pins:
Shielded center conductor to Pin 1 of the plug (mic hi)
RED wire to Pin 2 (PTT)
Black wire to Pin 3 (PTT ground)
Shield to Pin 4 (mic lo)

You are making progress. Keep us posted.

Boonton made the S1339A (analog) and the S1340A (digital) for Motorola.

I previously owned a S1339A and it is identical inside to a Boonton 92E. I have not seen the inside of a S1340A. I think it is same as a 42BD but not certain.

Millivac and Ballantine also made RF millivolt meters. The Millivac 823B is a good analog mirrored scale meter. Dont see these as often as the Boontons. Key is to make sure you get a good probe and probe accessories with which ever one you buy. Probes can sell for as much or more than the voltmeter.

Probe diodes (usually two in a doubler config) are proprietary and often are burned out as people dont understand the rf voltage limitation. Most of these probes will read 1Ghz, but can replace the diodes with germanium signal and recal the unit and be close enough for KW hybrid frequency ranges.

Probes usually come with a 50 ohm BNC termination adapter and a straight thru BNC adapter and of course you will need the 40db adapter (100:1 voltage divider) to read above 3 volts (driver tube plate and finals control grids rf drive levels). Before I could find a good 40dB adapter I used my Heath VTVM and PK-3 probe to measure Driver tube plate and 6146 control grids rf voltage. That works just fine. Where the VTVM and RF probe fall down is at the lower signal levels.

I think Dick W0NTA is a Millivac man and Ken K4EAA is a Ballentine man.

Thanks. The marker signal is also slow to recover, so the problem is not the antenna relay. At least I won't go down that dead end. However, replacing the driver tube made no improvement. In fact, the problem persists even if the filaments are turned off. I think I recall you saying that there are some biasing circuits around the driver tube that could cause this sort of problem. Can you direct me a little more? I have a scope and DVM.
Thanks. Al K2QU

How many hams need a RF milivolt meter that works above 250MHz?

There are a lot of Boonton meters on eBay that are missing the probes. When loose probes are offered on eBay they are expensive and there really is no guarantee they work.

The problem with the probes is the MAGIC DIODES.

I have been studying how to may reasonable replacement probes. But currently I cannot test above 250MHz.

I know how the probes work and I am building a copy of the 2500 calibrator. This calibrates the meter not the probes.

The probes are calibrated at 1MHz.

I'm thinking about a chopper replacement for the earlier meters also. That is the high failure item. There is a design for a replacement input board that looks good.

I'm replacing the HV caps in the 530. I have not pulled the originals but I don't see a polarity mark. I know these are connected in series. Just want to confirm, the red goes to the positive side to the first cap, the blue wire comes off the negative and goes over to the positive of the next cap, finally the black comes off the negative. Just want to make sure before I jump on the job.

Thanks Brian kb4mng

"Most of these probes will read 1Ghz, but can replace the diodes with germanium signal and recal the unit and be close enough for KW hybrid frequency ranges."

Where does my post say anything about needing to measure above 250mhz??????

I clearly stated that damaged probes can be repaired by using germanium signal diodes for the work a KW hybrid owner will want to do.

Very easy to obtain a very accurate calibrator. Every HP-435A/B Microwatt meter has a nice front panel calibrated 50mhz 0 dBm (224mv) output. Can buy these meters all the time for around $50 bucks without the probe. I bought two more at Dayton last year and bought one off the HP reflector by asking. Just check to see that the cal screw access cover paint hasnt been disturbed. Dont need the meter to work just the power supply and the calibrator module. Take the output into your step attenuator and can cal the lower ranges of your RF millivolt meter.

If you want to build a simple rf voltage calibrator go to W1GHZ website and see his RF power reference kit. I built it first before became aware of using the HP435 or similar. http://w1ghz.org/10g/10g_home.htm http://w1ghz.org/10g/10g_home.htm

Yes if the Driver tube is slow to transition from operating bias to cutoff bias you will have cathode current flowing and it will cause IR drop across R35 which will forward bias D2 protection diode and it will shunt RF signal voltage at Gate 1 of Q1 RF amp mosfet protecting it from damage from your internal Driver stage transmit RF output.

I know you replaced RL-1 which is the normal culprit, but could still be something going on with RB1 and RLR. RB1 is the dc bias for Q1 RF amp and RLR turns on switch Q5 that grounds the Source leads for all the front end active devices. You could meter both of these on the RF board to see if they transition instantly. In RX mode RB-1 will be approx 1.0vdc and RLR will be approx 8.9vdc. May be hard to do this with a DMM as wont have much time to watch it count and settle out. Another reason why I and Mike continue to hammer home a good old fashioned Heath or similar VTVM for KW hybrid work.

I suppose could also wiggle the associated Molex connectors or very carefully remove and clean them. Would include Conn 5,6,7 on Audio Board and Conn 3 and 8 on RF board.

If had a good RF sig gen could also inject 8.830mhz at RIF TP-2 and see if good audio level and S-meter indication during that 5 second delay. If so you would know the problem is on the RF board and not IF board.

OK, I sent you the picture to your address.

So now the center terminal has the black wire from the cable.
The only thing left is the normally closed (white/green) wire connected to nothing.
Is this the grounded side that you were referring to?
Here's the part that may be the most confusing for me. looking at the schematic. The center common switch shows that it goes to ground, and there is no wire for that. Like it's grounded to the base or something, inside the handle.
The terminal strip shows terminal A is grounded. There's nothing on that terminal now.
Terminal B has the black wire from the cable.
Terminal C has the red wire and the yellow wire.
The white/green wire was originally connected to the terminal B.

Terry,

You never said anything about needing a probe that works above 250MHz.

I'm just wondering if it would be worth my time to make probes for these meters that will work up to 250MHz.

I have Tektronics calibrator good to 5mV. I also have a working Boonton 93A. Probe calibration is done at 1MHz.

The reason I am thinking about this is that probably 9 out of 10 Boonton 92s offered on eBay are minus the probes.

And their working condition is really unknown.

OK I mis-understood you when 250mhz comes right on heels of what I posted. I thought it was a challenge and not a question. If a question you are the only one who can say if you need a RF millivolt meter that has a calibrated frequency response greater than 250mhz. Even Heathkit rated their 309C and PK-3 rf probes to 250mhz. Depends of course on what you work on. I typically dont work on anything above 2 meters and not much of that anymore.

Boonton has a low frequency probe but seldom see them. It is a 91-4C at 1khz to 250mhz operating range. I would like to have one and have posted couple of times on QTH and QRZ and came up empty.

If you use the 40dB capacitive divider the Boontons are good up to 700mhz instead of 1.2ghz.

I dont know where you are getting the probes are calibrated at 1mhz? Probes are always calibrated with the instrument to be used with. The periodic calibration of the meter and probe combo if done by the Boonton Model 26A calibrator is done at 1mhz as that is the Calibrator output frequency. No idea why they made a 1 mhz calibrator other than easier to build. I prefer to use the HP435A/B 50mhz calibrator. Can use it for your RV millivolt meter, your O-scope, and your freq counter. Actually a 14 mhz calibration frequency would serve my needs quite well for Hybrid work.

If you look at the service manual for the 92E you will see Probe Testing is done at much higher frequencies than 1 mhz. That testing includes SWR and Frequency Response measurement. The testing frequency for that is done with a variable 10mhz to 1200mhz frequency range signal source ie a high end calibrated RF signal generator and not a 1mhz calibrator.

One good thing about the Boonton probes is that the input capacitance ranges from approx 0.8pf to 1.5pf so wont be pulling or loading any oscillators.

Yes people strip off the probes on these just as they do on the HP power meters and of course you never know if any RF millivolt meter or probe is any good off Ebay or any other source. You take a chance when you buy one just like any other used and vintage electronic purchase so must understand your right of return.

Larry,

I got the picture. That matches the diagram I sent to you.

Just tape off or cover that white/green wire so it doesn't touch anything
or remove it completely. It is the NC (Normally Closed) side of the switch
that would ground the mic when the PTT is released.

If you look at the diagram you will see that mic pins 1 & 2 at the top of
the mas are connected together and, IIRC, that will short one side of the
mic element to ground.

It has been a long time since I opened up the mast of one of those stands
so I do not recall how they are wired. Frankly, I use an ohm meter to
investigate, and later check, my work. I would put your ohm meter on the
suspect wires/connections and see if there are any shorts and to verify the
PTT switch operation.

Terry,

My point was 250MHz is good enough for most ham radio work. And we can make probes that will work OK to 250MHz.

The calibration is a separate problem. As you said the meter is calibrated with the probe. How many hams will probably have a RF reference standard?

The 1MHz testing is just what I have read about calibrating using the Model 26A test reference.

I have a Tek 191 scope calibrator that is good to 100MHz.

My real question is it worth the effort to make these meters usable for people with limited recourses? Or does the average ham need any more than a Heath RF probe? Both 1 diode and 3 diode probes. They are no problem to make.

If a question you are the only one who can say if you need a RF millivolt meter that has a calibrated frequency response greater than 250mhz. Even Heathkit rated their 309C and PK-3 rf probes to 250mhz. Depends of course on what you work on. I typically dont work on anything above 2 meters and not much of that anymore.

Boonton has a low frequency probe but seldom see them. It is a 91-4C at 1khz to 250mhz operating range. I would like to have one and have posted couple of times on QTH and QRZ and came up empty.

If you use the 40dB capacitive divider the Boontons are good up to 700mhz instead of 1.2ghz.

I dont know where you are getting the probes are calibrated at 1mhz? Probes are always calibrated with the instrument to be used with. The periodic calibration of the meter and probe combo if done by the Boonton Model 26A calibrator is done at 1mhz as that is the Calibrator output frequency. No idea why they made a 1 mhz calibrator other than easier to build. I prefer to use the HP435A/B 50mhz calibrator. Can use it for your RV millivolt

meter, your O-scope, and your freq counter. Actually a 14 mhz calibration frequency would serve my needs quite well for Hybrid work.

If you look at the service manual for the 92E you will see Probe Testing is done at much higher frequencies than 1 mhz. That testing includes SWR and Frequency Response measurement. The testing frequency for that is done with a variable 10mhz to 1200mhz frequency range signal source ie a high end calibrated RF signal generator and not a 1mhz calibrator.

One good thing about the Boonton probes is that the input capacitance ranges from approx 0.8pf to 1.5pf so wont be pulling or loading any oscillators.

Yes people strip off the probes on these just as they do on the HP power meters and of course you never know if any RF millivolt meter or probe is any good off Ebay or any other source. You take a chance when you buy one just like any other used and vintage electronic purchase so must understand your right of return.

I forgot to mention one other option and that is a refurbed HP-410C VTVM with the "active" 11036A RF probe (It has diode tube in the probe). This kills two birds with one stone as you end up with a 100meg ohm input Z VTVM that allows AGC and ALC bus work and a RF millivolt meter. Not cheap but a real nice piece of test gear.

I have the 100:1 HP453A capacitive divider probe and the 11042A RF Tee for mine, but seldom use them. I can actually measure the RF voltage (greater than 500rf volts) across the KW Hybrid tank capacitor with this meter. The limitation is that the active AC probe doesnt go down as low as the Boonton or other RF millivolt meters. Its lowest range is approx 500mv where the Boonton is 1mv. About only thing you could not measure would be the TIF signal level, but could read RF drive level at TX Mixer and Driver tube plate and 6146 control grids.

You can read all but TIF with Heath VTVM and a 309C and PK-3. Just have to keep the probes straight in your mind. I placed dymo labels on mine so I dont accidently reach for the wrong one. Of course with right O-scope and probe combo can read all of the levels. I just got a P5100 probe so I can do some tank circuit work with my O-scope.

Wire Wrap is used throughout the telephone industry wired and wireless. There is a proper method by bell standards. No niche in the wire when stripping, at least enough wire to produce 5 wraps on the post which equates to about an inch and a half of bare wire. They make hand wrap tools for a number of gauges as well as hand type guns and an electric wrap gun. I have used all three in my 40 year telephone career as well as soldering in the older central offices. Brad KB2CHY

To: TS-520_820_530_830@yahoogroups.com
Subject: [TS-520_820_530_830] RE: Wire wrap

No KW factory did not solder any of the wire wraps.

Wire wrap is a very old and reliable termination method. If done correctly never a reason to solder. The soft copper actually deforms against the sharp edges of the hardened post and oxide coating is broken and very high contact pressure is developed and typical contact resistance is < 1.0 milliohms. The wraps are actually gas tight so connections are good for 40 plus years. Navy avionics did a lot of testing on this type of termination. Can find some interesting white papers on this subject.

When you remove a wire wrap must cut off all the old wire from the lead and not attempt to re-use it in any manner as it has work hardened. You can strip back and rewrap with proper size hand tool available from Jonard and Cooper and others, but I just file the post to brite metal and make couple of wraps near top and tack solder the lead back on. .

From: Joseph Stiles
Topic: 48058 Message: 48069

Brian,

It does not really matter what color wire(maybe prior work)...as long as it goes to the same place. IF... the HV caps are original then: with the rig bottom up, front facing you.. the HV cap on (now your right), the NEG which should be marked with a black identification
spot on the connector (black wire)...goes to the ground post...the Positive (+) RED goes to the other HV caps BLACK terminal.....the POSITIVE (red wire) goes to the rectifier board.

It is not that difficult. Make a drawing or take pictures.....every Electrolytic capacitor is marked in some way to indicate...which terminal which is negative/positive. If in doubt...may I suggest a review of some basic capacitor markings

Just make note of the orientation and wire color or the originals....and reinstall according to
that. You may have to substitute another color wire..as from memory...they may be soldered to the old HV caps. Unsoldering and unwrapping them may break of too much wire to re-use.

All you need to do is pay attention...the old HV caps ARE marked for polarity.

48070. Kenwood Hybrid Net Update - March 9, 2014

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-09 19:21:12 UTC
From: Mark Gilger
Topic: 48070 Message: 48070

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Dayton Hamvention Kenwood Legacy Forum:
This year will be the first year for the Kenwood
Hybrid Legacy Forum to be held at the Dayton
Hamvention. The forum will be Sunday May 18th.,
room #2, 10:30 □ 11:30. The following preliminary agenda has been proposed:

* History of the legacy products.
* Resource help with parts, documentation, etc..
* SDR integration into the legacy line.
* Rewinding a TS-830 L41 coil.
* Tips & Hints.
* Questions and Answer Technical Session

We hope to see you there.

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday 40 meter net had 25 stations
checking in under good band conditions. There
were 9 new stations checking in, KF9CE, KA8GUN,
KD9WNQ, KD2DQA, N9LGQ, N9VVP, W9DGK, KC9ECI, and
KD8LCM. We had the following number of radios checking in.

5 running TS-520(x)
3 running TS-530(x)
2 running TS-820(x)
2 running TS-830S

I was running my TS-830s with an L4B amplifier.

The Sunday 20 meter net we had 30 check-in under
good band conditions. There were 4 new check-ins,
WB0CJB, KC9WKY, N8VKX, and KD0VEP. We had the following number of radios.

3 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
5 running TS-830S

I was running my TS-820s twins, the TS-820s & R820.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85
March 2014, Saturday□s net total = 45, Sunday□s total = 30 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

48072. TS-520 Frequency Jump on Transmit

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-09 19:31:01 UTC
From: <bgaston@...>
Topic: 48072 Message: 48072

Have had this happen several times in the last few days--a new problem on what has been a great, stable radio. I always let it warm up for about an hour before running it, and am OK with some slight, slow drifts that the waterfall can follow. This is just absurd.

First it started on JT-65, running about 10 watts, the radio would be rock stable for 2-3 QSOs, then after a transmit cycle, I'd click back to receive and be 5-10 khz away from where I hit transmit. I'd go find the waterfall again, get through 1-2 transmit cycles, and it would jump AGAIN, and the waterfall would be where I had originally started out the first time on the dial--said another way, it jumps equally back the other direction. No, I am NOT bumping the VFO.

Another time it's done it, it did the same 5khz jump one way on SSB, go find the pileup again on the dial, call again, silence. Then go find them again where I started.

It's done it also while running PSK, and the waterfall jumps 1-2khz one direction, then slowwwwwwly shifts back to where it was. Has also made the 5Khz jump all the way over to the JT-65 segment then back to PSK.
Any ideas? I originally cleaned the VFO and sprayed the wiper with De-Oxit when I got the radio and went through the initial "pulling it out of mothballs" process. Have had no clicks, pops, or magic smoke. From my limited knowledge, it almost seems to me to be a capacitor that might be failing somewhere, or something funny going on in the VFO itself.

Thanks in advance guys.

Average KW Hybrid owner can get by just fine with VTVM or DMM and classic germanium signal diode probes. Just cant read TIF signal level from the IF board. This has been stated here over and over again by me and others. I cant tell you how many times I and at least Mike W5RKL counsel new hams and new KW hybrid owners that have no test gear that the Heath IM-18 VTVM and associated probes (or similar model) should be their very first test gear purchase.
Wes Will posted and asked about the Motorola RF millivolt meter brand. That is what I responded to and not to whether he needed an RF millivolt meter or not. Need is a relative term. I would not be without one.

For those who like to build the AD8307 log chip based analog power meter and now the PIC based version is also a very inexpensive way to go. With a Goggle search can find QEX and QST and numerous other articles on how to build this meter. Problem with this route is still need means to calibrate it and I have already provided two easy ways to do that.

From: <wagstw46@...>
Topic: 48058 Message: 48074

Are you using the Black Nichicon GN type caps that Ken K4EAA sells?

If so, be careful and do not mistake the cross hatch pattern embossed on the terminal rivet head as the positive terminal. It is the Negative terminal.

Pay attention to the polarity stripe on the capacitor vinyl cover. The grey stripe denotes the negative terminal. The oblong or oval circles are not zeros they are minus signs on that polarity stripe.

48075. TS-530 final bandswith coupler, lost alignment.

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-09 20:55:16 UTC
From: <donhoover@...>
Topic: 48075 Message: 48075

Ok, this TS-530 of mine I am trying to rescue and give a loving home for another 20 years, needs a new bandswitch coupler in the finals. I have taken the old plastic one out that was clearly cracked in a couple of places and pretty much not working, and I have a nice new brass one I got from Ken/K4EAA to replace it with.

However, the old split coupler had apparently gotten so loose on this radio that the bandswitch rod was able to turn without turning the corresponding switch rod its supposed to be coupled with in the finals section, so I was not able to mark for sure how the rod ends were supposed to match up before installing this coupler.

How can I figure out the proper matchup of the two rod peices before I tighten up the new coupler? Is there a way to visually figure out the position of that switch in the finals section and then match the position of the bandswitch to the same band?

Thanks!

Don
WS4E.

48077. Re: [TS-520_820_530_830] TS-530 final bandswith coupler, lost alignment.

Topic: 48075 Message: 48077

Don,

Ok...let's start at the final cage: NO POWER....and unplugged...check for HV...none OK

looking at S-22...the tank coil selector switch in the final cage.. there are 2 flat areas on the
short piece of shaft...with the front of the rig to your left...and the right side of the rig facing you
...there should be one flat facing you...or at 3 o'clock...and another one facing down...or 6 o'clock.

Now the switch wafers:

You will notice that there is a white plastic middle...look for the indented circle...there are two..but one is more indented than the other...all those " indented circles"must face to "nine o'clock"(front of rig facing you....top side up)...also the flats of where the shaft goes through should be at 3 & 9 o'clock...round parts 12 & 6 o'clock.

Take shaft...with knob attached....white mark of band switch knob facing "10" that's TEN....NOT 10 meters...and slid through front panel...wafer switches and onto new band switch coupler.

Make sure and check your work...and check your work again.....snug up set screws. Check for proper operation

> The reason I am thinking about this is that probably 9 out of 10 Boonton 92s offered on eBay are minus the probes.

Bingo. And why I am NOT looking at the auction sites for this Motorola meter. The seller will verify the probe comes with, or no sale. I'm NOT going to be putzing around looking for probes. Buildng one, perhaps. Doing a 3-diode probe for my Heathkit VTVM right now. (RE-building one I smoked, actually. Got onto the wrong circuit and boy howdy, even three diodes aren't going to carry that much current. Cooked the diodes, cooked the capacitor. The resistor got hot enough that it isn't anywhere close to 4.7M Ohms. Almost 12 megs, now, and just a little on the brown side.... So, I'm rebuilding it.

Are the probes for the Boontons and their ilk home-brewable? They frankly shouldn't be that much different than the VTVM diode probes. (I'm NOT talking about he active vacuum tube diode probes, obviously.) What's under the hood of a Boonton probe?

Terry: THANKS for the calibrator ideas. Why the idea of using the cal circuit of one of these other meters didn't cross my mind on it's own? I guess I'm not all that smart, all I can see. But now you've mentioned it there are obviously a lot of choices. Finding the cheapest one and getting my hands on it is the next step.

I'm also interested in the Raspberry Pi and Arduino meter options. I've been avoiding diving into Pi because I've already got enough irons in the fire, but making a meter replacement from one might be enough to tip me over that edge.

Thanks for the ideas.

We used wirewrap extensively in the 70's and 80's in the engineering department ... for prototyping new circuits and building of production test equipment. The advent of cheap printed circuit boards in small qty, as well as circuit-layout software, doomed its use in that area. Wirewrap was so reliable, it was also used extensively in the nav. computers aboard Navy submarines. I still like to use it at home.

From: <bgaston@...>
Topic: 48072 Message: 48082

Update: Did some more trials. Looks like after 1-2 transmit cycles, the receiver "switches back" to EXACTLY where it was before the "jump". For example, trying on PSK31, the transmit cycle ends, and I'm out in left field with no signals nearby. Cycle a test tone transmit once or twice, and I flip back to EXACTLY back where I started in the first place, with the traces on the SAME QSOs.

Hi Guys,

acquired my first TS-530SP and DFC-230 a couple of weeks ago.
Has connected DFC-230 with TS-530SP and find out that either XIT or RIT
on trcvx is not working....:(Is there any modifications where you have to unsoldered
some contacts on VFO cord of DC 230 in order to have fully functional RIT/XIT...

Also if i use DFC-230 with probale and new additional hybrid as an TS-830S, am i going to
have same problem ?

In nutshell, how compatible is DFC-230 with TS-530S and/or TS-830S??
(That is meant, using it as an + external VFO in place of original VFO 230/240 ??)
When studying the diagrams there are some "extra" contacts not being used when
TS-530SP or TS-830S are used with Original VFO 240 ....

Any clue guys?

Thanks Nermin S58DX

p.s.what a radio, what a receiver, reliving at least :)
Has TS-2000, TS-870S, TS-930S, TS-480S....
All digital except TS-930S :)

With your 3 diode PK-3 did you use a dc blocking/coupling cap as the first element?

Sounds like you may have been measuring something like Driver tube plate RF drive voltage where there is 340vdc (which is fine thing to do) to get the kind of current that would do that level of damage. Need something on order of .001uf cap (value not too critical) at minimum of 500 wvdc rating. I would use a 1kv wvdc cap.

1. What does the radio do in ICAS modes it was designed for ie SSB and CW?

2. I know you said you cleaned the VFO air variable rotor shaft wiper contact, but sometimes it takes multiple cleanings to restore good low resistance contact thru lock to lock rotation.

3. What is the regulated 9vdc doing at the VFO?

4. Try powering the VFO with 9vdc bench supply or a 9vdc transistor battery.

5. Try cleaning the 8/9 jumper plug to socket interface or temporarily tacking a jumper across the socket pins.

Precisely what happened, but it wasn't on purpose.... Probe cable is a little stiff, and when I laid it down to reach for a tool, it un-kinked itself and the tip slipped onto the circuit board. It's right where driver plate feed is, and that's when I heard the zap. No damage to the radio, just the probe. Too small a working voltage cap, it was just a 250 I had laying around in the junkbox. Poof.

New probe parts will be a LOT beefier....

http://www.cliftonlaboratories.com/diodes_for_rf_probes.htm
http://members.shaw.ca/novotill/RfProbeSensorMvUw/index.htm

This should help you. I dont normally share this secret stuff!

Yes you can homebrew a probe or repair a probe for a commercial RF millivolt meter like a Boonton. For the Boonton and Motorola meters you will need two diodes and series resistors and a capacitive center tap in the probe as you are feeding a differential amp or chopper.

I have replaced the diodes in burned out Boonton probes (bought a bad one at Dayton two years ago!). I have experimented with 1n34, 1n60, 1n270 and several Schottky types. Key is to try to match them both up on the bench. You will also have to perform alignment after changing out the original diodes.

I have two 92E Boonton meters here and three probes. Two with factory diodes and one I repaired. Both of the two factory probes have different low ohmic value series resistors so OEM diodes are clearly slightly different. Remember we are talking about a RF meter/probe designed to measure up to 1.2ghz calibrated. Accuracy up to 100mhz is 0.09db and up to 1ghz is 0.27dB.

I have compared the original diode probe with the repaired one with 1N5711 diodes in it and the two read pretty close at 14.200 mhz.(less than 0.25dB measuring 0dBm or 224mv). As I go up in freq they start to differ and pretty quickly. At 100mhz approx 0.50dB. Perhaps if I had used factory matched HP diodes would be better?

At low frequencies you will be measuring in KW hybrid work I dont think the difference from the original proprietary diodes will bother you too much. Most of the KW levels you will want to measure and adjust will have a +/- 1dB tolerance. For example 300mv 8.830mhz Carrier Osc needs to be from approx 267mv to 377mv. The 1.0v 8.375mhz VBT Osc needs to be from 890mv to 1122mv.

OK-- Driver Tube plate is highest place both DC and RF you will want to measure with your homebrew PK-3 RF probe. Depending on KW model will see something between 60 to 70rms rf volts. There is a reason why the TX Level Diagrams stop at the control grids of the 6146 finals (approx 45 to 47 rf volts).

One problem measuring RF drive levels on at TS520 or TS520S with wire wrap terminal posts is it is very easy for the probe tip to slip off the head of the terminal post and you have to watch where you are probing and other eye on the meter. I made a cheap test adapter by taking piece of 14 gauge bare copper wire and two bare butt splices. I soldered butt splices on each end of about 3 to 4 inches of the wire and then heat shrinked the thing. I can slip one open end of this test adapter over any of the wire wrap terminal post and then connect RF probe to the top end with a short mini-grabber test lead. Now my rf voltage probing is hands free and can focus on the meter switch and meter indication without slipping off the top of the terminal post down into the board and contacting or bridging or shorting something that results in smoke.

Of course never try to look at the RF voltage at the Plate of the 6146 finals as you will have something on order of 850vdc and 535rf volts. The 850vdc wont hurt the PK-3 if it has the proper blocking/coupling cap, but the diode PIV will be exceeded. Will also have over 500 rf volts across the VC-1 tank cap. OK to measure across the Plate load cap or center conductor of the SO-239 (across 50 ohm dummy load) and will see approx 71rf volts at 100 watts.

If you are curious about the RF voltage across the Tank circuit (the Plate tuning capacitor and the tapped Tank coil) can approximate it by:

Final tube plate DC voltage X .90 X .707 = RF rms volts. So for your KW hybrid will be approx :

850vdc x .90 x .707 = 541rms RF volts

I have confirmed this by measurement with a HP-410C and 100:1 probe and my O-scope and P5100 hv probe.
It is fun when the theory and math prove out by measurement, but typically no reason to measure RF voltage levels inside the PA cage.

I drew up a safety diagram showing how to ground the plate choke to ground for safety in the finals section.

I had read about what to do for a while, but it did not make much sense exactly what the procedure that people were describing was until I actually got around to working in the finals section and saw it with my own eyes. Hopefully, this will help people see what they need to do BEFORE they ever even have to open up their finals section themselves and they will be fully prepared.

Let me know if its correct or any issues. I put this in the files section where people can find it.

Ron:

I think you are asking about a diode detector to use with your new Wavetek sweep gen?

If so, nice to have the Wavetek detector like the D-151. I use one with my Sweep gen. I like them because BNC connectors on each end so easy to place in line. However, you dont see them often and a little pricey. I got mine off Ebay.

Can use just about any diode detector. Can build one on piece of perfboard or Radio Shack project board. There is a schematic for the detector that KW recommends in every Service Manual. I built one and used it before I got the D-151 unit.

If you dont have the service manual need to download and study as one of first steps in aligning a TS520 will be to check the Rx and Tx BPF alignment and manual shows the diode detector and how to connect and the expected response curve. I am pretty sure I sent you picture of a TS520 BPF response curve that I ran with a Wavetek sweeper.

I highly recommend you also connect a good standard RF sig gen into the Marker input of the Wavetek as you will need to be able to see the filter Fc at minimum to make your adjustments. The sweepers internal markers are of no use for KW filters.

OK the 2002 will serve fine. If you dont have the manual easy to find and download. I think Fig 4 shows how to connect the Detector and O-scope to test the unit.

The KW detector circuit works well, but as I mentioned you can get by with a single diode crystal detector and still have enough scope deflection. Some of the crystal detectors (classic HP423) you will find on Ebay are rated at 10 Mhz to the 20Ghz range but will work for KW hybrid IF. Some will have BNC on one end and Type N or SMA connectors on the other end so you will have to buy adapters if you buy one of those detectors.

If you have BNC to mini-grabber test leads can just hook a germanium signal diode in series in the hot lead to use the sweeper for now.

You will also see under the Typical Test Set-up diagrams Matching Units shown between the sweeper RF output and the DUT and for KW hybrid filter sweeping you wont need to worry about that.

You will be running with both the frequency indicators (green and red start stop pointers) near the far left end of the dial and most likely not accurate. I use Freq Counter to get it close to 8 mhz range.

Not hard just have to get comfortable with the Sweeper controls and the X-Y function on your O-scope. If you have a spare filter can learn how to use the sweeper without connecting into your TS520. Should terminate filter with fixed resistors (one in series and 50 ohm in shunt) that matches the filter input/output Z or can use a pot and connect sweeper to the wiper and adjust pot for peak. Service manual calls out the various xtal filter impedances.

I have to tell you in my experience seldom find the Tx BPF very far out but do find people have messed with the Rx BPF on the TS520S rigs. Just remember you are talking about coils on the IF and RF boards here. Two on the IF board and one on the RF board in each case. The manual diagrams call them out.

I think Paragraph 2.4 in your manual tells that it is a Type N connector. You will need a Type N to BNC adapter. Very common on Ebay and at hamfests. I thought you had a Wavetek 3001/3002 RF Sig gen and it has same RF output connector?

Type N is used as the generator ranges up to 2500 mhz. No problem using the adapter to BNC patch cables for KW hybrid filter sweeping. Highest frequency you could get involved with is approx 40mhz (TS530/830 PLL BPF).

Topic: 48031 Message: 48104

OK, I've got this figured out now. Wires are set up as you specified and the cable connector side done as well.

Here's how it's set up now, just in case I missed something:
Pin 1: Shielded center wire directly connected to mic (black wire)
Pin 2: red wire, connected to post 3 (NO side of switch) with yellow wire.
Pin 3: Black wire, connected to the center post of terminal.
Pin 4: shield wire, directly connected to mic (green wire)

I tested and verified connections in the cable to ensure there were no shorts and good connectivity on all pins/wires going to the base.
In testing the mic, it keys up nicely but I get nothing on the meter when speaking.
(Mic gain set at 5)
Am I missing anything?

Larry,

What meter are you referencing when you say you get nothing?

I am assuming that you have tried another mic on the rig using the current settings and it works. Is that correcct?

Did the D104 work before you started your rewiring project?

Do you have an AC millivolt meter or a DMM/VTVM (at least 10 megOhm input) with a very low AC scale? If so, remove the D104 head from the stand and connect ithe meter across the mic element in the head and speak/whistle into the mic (check the schematic for the correct pins in the mic head). You should see an indication on the meter if the mic is putting out anything.

Let us know what you find.

Ken,

assuming that the microphone/wiring are correctly working.....

To what position do you have the meter selector switch set to?

You should have it set to "ALC." With rig properly tuned up...switch to which ever sideband...
key rig...and while speaking in a normal tone of voice a few inches from the microphone....rotate the "mic" control clockwise until the meter needle just bounces up.

This is covered in the operator manual

If so, remove the D104 head from the stand and connect ithe meter across the mic element in the head and speak/whistle into the mic (check the schematic for the correct pins in the mic head). You should see an indication on the meter if the mic is putting out anything.

Jim,

I do not think that the combination will work.

The Remote VFO-820 has the same VFO as the TS-820(S) The VFO has a frequency spread of 5.0 mHz to 5.5 mHz.

The VFO in the 830 has a VFO with a frequency spread of 5.5 mHz to 6.0 mHz.

Jim,

As Joe said the VFO-820 has a different frequency range then the TS-830 internal VFO. Therefore, the VFO-820 will not work with the TS-830. The only Kenwood external/remote VFO's that will work with the TS-830 are the VFO-230 and VFO-240.

Larry,

The meter, in receive, will only display variations in the IF Unit's AGC voltage based on the varying strength of the receive signal. The meter switch is disabled in receive, hence none of the meter switch position will work in receive. Switching to transmit, the meter switch is enabled, displaying the appropriate indications on the meter.

Does the meter work in receive, i.e., indicate S Unit based on the receive signal? Also, in receive, does the meter rise above zero and peg fully to the right when the RF gain control is rotated fully CCW? If so then the meter itself is working as it should.

I may have missed it but what band or bands are you experiencing lack of ALC in sideband transmit?

Are you experiencing the lack of ALC during tune up or during normal sideband transmissions?

What position do you have the MIC gain set at during normal sideband transmissions?

If tune up produces normal ALC indication but normal sideband with the MIC gains set between 9 and 11 o'clock, there is no ALC indication, it's quite possible the microphone element OR wiring to the element is bad. It's no unusual for old D-104 microphone elements to fail due to age and/or storage environment. Moisture can ruin a microphone element.

Ken,
The meter I was referring to is the S meter on the rig.

This is my first rig and mic. Both were purchased separately. I cannot confirm that the mic worked before other than the word of the previous owner. Testing the mic head does show that the head is indeed working. I did not do any testing of the mic before the re-wiring. The rig was used exclusively for CW from the previous owner.

Jon,
Thanks, while not an old time to the group I am an old timer and I like the tubes also.
First thing I need to know is where to find web information on how to use the 530.
My group history tour taught me how to tune it, but it will not stay tuned. Once I retune it works for a short time, just minutes. I was thinking that the 6146's might be weak or something times out on the heater.

Ben,

What do you mean when you say your TS-530 will not stay tuned? Be more precise in your explanation please.

There is no timer on the tube filaments.

The KW hybrids do not have a broadband final as the modern solid state transceivers do. If you change frequencies by a substantial amount, say 35 to 50Khz then the transmitter should be tuned again.

Try this simple test. Follow the test on 20 meters.

1. Set the Mode switch to TUNE
2. Connect the 530 to a 50 ohm dummy load (hopefully you have one as all ham stations should have a 50 ohm dummy load with a power rating of at least 200 watts)
3. Set the Meter switch to ALC
4. Set the CAR control between 9 and 10 o'clock
5. Set the DRIVE control to 12 o'clock
6. Flip the SEND switch UP, that will key the transmitter
7. Adjust the DRIVE control for a peak indication on the 530's meter. If the meter peg fully to the right, reduce the CAR control (CCW) so the meter points to approximately 12 o'clock and continue adjusting the DRIVE control for a peak meter indication.

Do not touch any controls, simply leave the transmitter keyed for 3 or 4 more seconds and watch the 530 meter. Does the meter start to drop back towards zero during those 3 to 4 extra seconds? If it does then the driver tube should be replaced. You do NOT have to change the final tubes if you only have to change the driver tube so don't waste money on final tubes simply because you changed the driver tubes.

Now if the ALC meter indication remains stable, it doesn't drop back toward zero after 3 or 4 seconds with the transmitter keyed in TUNE mode then the driver tube is fine.

If, after completing the normal tune up with maximum output, power output starts to drop off after a few minutes then it's possible the final tube(s) may need replacing. If you have to replace the final tubes, first don't waste you money on matched tube, you will not achieve any benefit by purchasing matched 6146B final tubes so don't let anyone convince you differently. Second, you will have to neutralize the final amplifier before using the 530 with the new final tubes. The procedure to neutralize the final amplifier is covered in the TS-530 operator's manual.

If you are using the "RF" meter setting, remember that meter switch setting does not have a meter scale and it only indicates relative power output. The RF meter switch indication is set by the rear panel "RF VOLT" pot as discussed in the 530's operator's manual.

Bennie,

Could you be a bit more specific about your rig not staying "tuned." Changing frequencies will cause your rig to get "out of tune" because the selected tank circuit and associated "stuff" is tuned to a specific frequency. Changing frequency (on same band) by several hundred kHz will cause an "out of tune" experience.

Check this with rig properly tuned up(dummy load please):

Check your HV(high voltage- indication available with front meter selector to HV) with rig in transmit...less than about 750VDC may indicate weak HV capacitors.

Check for falling DRIVE LEVEL(ALC) on key down(transmit)...usually indicates failing 12BY7A driver tube.

Falling plate current(Ip) on key down usually indicates failing final amplifier tubes.

The heater circuit affects both the driver and the final amplifier tubes. I doubt that this is a problem, otherwise I do not think that you would get proper output due to a malfunctional heater circuit...but anything's possible.

Remember....these rigs require operator intervention....they are not plug-n-play

Ben,

I forgot to comment about "how to use the 530". All you need to know about how to tune and operate the TS-530 is in the TS-530's operator's manual. If you do not have the 530 operator's manual then you need to download it and spend some time studying it so you can learn what the function of each control is and how to use them. All too often people buy KW hybrids but the manuals don't come with the radio. Instead of finding the manual, the buyer plugs the radio in and starts attempting to operate it. When something doesn't work as the buyer thinks it should, instead of obtaining and consulting the operator's manual, the start asking question when it's quite possible the answer to their question is in the operator's manual

Larry,

A previous operator who used the 520 exclusive on CW will not have anything to do with the problem you are having.

Does the meter work with the meter switch set to ALC during TUNE mode transmitter tuning? If so then it's not the meter that's your problem.

As I asked before, does the meter rise fully to the right when the RF Gain control is rotated fully CCW?

I'm brand new to amateur radio and this group and I've been lurking here and reading all the Q&A with great interest. So much to know beyond answering most of 50 questions correctly! In addition to the forum, I found (on someone's recommendation) the http://www.k4eaa.com/faq.htm site. Holy cow, what a great place to find great and practical information. Not just *how* to do something but *why* it should be done. I'm sure there are other great resources out there that I have yet to discover so I'm going to do a lot of reading in this group's archives, download and read manuals and listen to the hard won wisdom of the folks with years of experience before I ask any dumb questions. I have not keyed up yet but I'd like to be as well informed as I can be when I do. Y'all keep up the good work - those of us with little experience are all benefiting.

Mac,

The TS-530 Remote VFO socket actually has "8" pins, 7 in a circle around the edge and one in the middle, just like the TS-830. You can see this by viewing the rear panel of your TS-530 and the schematic in the TS-530 and TS-830 operator's manual.

Bennie, when the tuning changes, does the plate current "dip" position change? (that's the same point as the RF "peaks", if the meter is reading RF). Or, does the output fall off?

If the latter, you should replace the 6146s ... (wouldn't hurt to check the driver tubes, too) the 6146s don't need to be a matched set, but, you will have to "neutralize" the new ones after installed. That's in the op manual.

If it's the former, it could be a multitude of things from a faulty drive signal to the 6146s, to a faulty antenna.

Web info for these rigs: the yahoo groups is good; also, a website called: www.mods.dk

Jon

P.S. The TS-530 is a great, great rig ... the TS-830 is the same rig, but, with a notch filter in the rcvr.

Jon,

That was a typo on my part. Had just looked at the manual and must have had the external VFO connector in mind.
I need the 7-pin DIN connector. Per the TS-830S manual, the XVTR connector is the 8-pin (7 around 1 in the center) and the ACSY connector is 7-pin (nothing in the center).

I need the ACSY connector. Someone mentioned Mouser, and I did find two, part number:

568-NYS323
Male 7-pin cable

Hopefully these will work, else I'll be getting back to you.

73,
Mac K6OVI

Tried the manual?

http://www.ixquick.com
(they aren't sending your IP address and associated searches to the government. I use ixquick by preference these days because it's none of Uncle's bees'-wax what I look for.)

Once there, search for
Kenwood manual vfo 230

The first link is

http://w0nta.com/Kenwood%20VFO-230%20Instruction%20Manual.pdf

The schematic and pin-outs are in there.

Jon,
Sorry to be picky but the 830 and 530 are not the same rigs, as per your "PS quote". They have physical similarity, but the circuitry is different . The 530s is\has single conversion architecture, so the output from the balance modulator and Q18 is 8.830MHz, and not 455Khz. The 830s is a double conversion.
Whilst there are some common traits, as an example the 530s RF board has missing components and connector, so one cannot simply swap RF boards between 530s and 830s without addition of parts.
The IF and AF boards are different. The 830s is a far more sort after radio, it has VBT, Notch filter and some novelty gimmicks (DH hold) in some sense it is a superior radio to the 530s. I wont get into the argument of gold label versus silver label.
I have two 530s, a 1 million series and a 3 million series. The circuits have been improved over time by Kenwood. Same as the service manuals, my original 1982 (530s) service manual is missing sections, compared to the 530s\sp service manual
Have a look at the service manual for both models and do a comparison, it is interesting on what you can see and a good way of learning.

"P.S. The TS-530 is a great,
great rig ... the TS-830 is the same rig, but, with a notch filter in the rcvr".

For the benefit of the newbies/inexperienced operators, the connector in question on the rear panel of the TS-830 is the "REMOTE" 7 pin DIN socket. The TS-830 does not have a socket labeled "ACSY". This is not being nit-picking but rather making sure the newbies/inexperienced hams/members are aware of what actual socket is being discussed here.

48137. New (to me) TS-520 with some issues.

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-13 03:59:24 UTC
From: <junkmailsux@...>
Topic: 48137 Message: 48137

I was given a Kenwood TS-520 in exchange for a website. When I opened it there was a huge mouse nest over the RF board. Wires had been chewed through and it was pretty "dirty". I've repaired the wires and cleaned it up. I've been a ham for almost a year and this is my first big radio. Up to now I've only had a BaoFeng UV-5R but it's just 2M/440.

Here's a list of issues that I've found so far. I'm hoping someone can help.

When I turn down the RF gain, the meter rises to max with RF at 4. Is that normal? Receives CW (and other tones on USB & LSB) well if JJY/WWV is ON and is fairly loud with the volume around 25%. When it’s off, I have to max the volume (and can still barely hear it) and never get anything but static. I'm hooked up to a 274(ish) foot square loop that works beautifully with my buddies Icom 706. Receives San Francisco Air Traffic Control (REALLY WELL) on ALL bands if JJY/WWV is ON. That's the ONLY voice transmission I've heard. Band 28 is 11M. How do I switch it back to 10M? I appreciate your time!!

Thanks,
Chad

I'm in a similar situation with a couple of 520S radios. I'm not an electronics engineer/tech or have test lab but interested and motivated to learn.
The service manual contains trouble shooting outlines but not much further detail - step 1 of no output--> final section lists 4 possible reasons but doesn't go in to how to test the 4 listed points. eg 1 Deterioration of the S2001A - without a valve tester or other test equipment how can I tell if they're the culprit? Aside from trying other valves!
I shall be searching this forum for procedures and steps to take but it would be useful to newcomers if there was trouble shooting guide - with a bit more detail than the kenwood service manual! As was pointed out earlier, there are only about 100 possible things it could be - but where to start and whats the logical order?
I will have a hand from a local ham with considerable experience but would like to understand the troubleshooting workflow for myself.
Here is the youtube clip I made to demo what is happening with the 520S
https://www.youtube.com/watch?v=1rIQ0cRThaU https://www.youtube.com/watch?v=1rIQ0cRThaU
I have purchased components to fix the first faulty 520s (different tx output fault) but looks like I may have to use these to fix what has been my "main" radio and order another batch!
I'll stock up on some parts for my 830S while I'm at it - or is that tempting fate?

The ALC meter does work when receiving.
And yes, the meter goes all the way over with the gain rotated fully CCW.

I think that at this time, unless someone has a good idea of what is going on, I'm going to put this on hold until I can verify this mic on another radio or I get another mic to verify the radio,

Larry,

Others on the list have advised you on the behavior of the TS-520 meter in receive ("S" meter) and in tune/transmit (ALC) so I'll only refer to the mic which can be tested independently from any rig.

As MIke mentioned, it is not uncommon for those old D-104 crystal elements to go bad. Do you have an oscilloscope? If so, unsolder the two wires from the mic element in the head and connect the 'scope probe directly to the element terminals and whistle. You should see the display change in response to your whistling. If you don't have a 'scope try putting whatever test meter you have (DMM, VTVM) on the lowest AC range (millivolts) and whistle. The meter reading/needle should fluctuate if the element is good.

Let's verify your wiring with some additional tests. Just to eliminate any shorts or miswiring, if you have not already done so, open the back of the mic head and unsolder the two wires from the mic element. Assemble the mic head to the stand. Set your meter to ohms for the following tests. Be sure the PTT bar is not depressed/locked on. It must be off/open for these tests unless otherwise indicated.

1. Check that one of the wires HAS continuity to pin 1 of the 4 pin plug.

2. Check that the other wire HAS continuity to pin 4 of the 4 pin plug.
3. Check that there is no short between the two wires in the mic head.
4. While the meter is connected across the wires press the PTT. There should be no short.
5. Check that there is NO continuity from EITHER wire to the case/stand.
6. Press the PTT and check that there is NO continuity from EITHER wire to the case/stand.
7. Check that there is NO continuity from EITHER wire to pin 3 of the 4 pin plug.
8. Press the PTT and verify NO continuity from EITHER wire to pin 3 of the 4 pin plug.
9. Check that there is NO continuity from EITHER wire to pin 2 of the 4 pin plug.
10. Press the PTT and verify NO continuity from EITHER wire to pin 2 of the 4 pin plug.

Please report your findings.

From: Mac Haszard
Topic: 48117 Message: 48142

To further clarify:

Mike is correct that the 830S does not have a socket labeled ACSY, the socket in question is labeled "remote connector".

I was referring to page 13 of the users manual which has a wiring diagram for the remote connector. For whatever reason, the manual describes the remote connector as the ACSY connector as opposed to the XVTR connector for the external VFO.

Nothing like clear, concise technical writing...!

The RF gain thing is pretty normal. Just leave it all the way up.

If you select a "normal" band (ie. not WWV) you need to tweak the drive control as well. This tunes part of the PA and the receive preselector. You'll hear a point where the noise comes up.

I'll give the 1980's Kenwood tech manual writers a pass. The original language was, no doubt, Japanese, and had to be translated. That's no mean feat.

Here's an illustration. At around the same time my TS-830S was being manufactured and documented, I visited a motorcycle repair shop that had begun importing the Yuasa brand motorcycle battery. To promote this new offering the shop displayed a huge, distributor-provided poster depicting a young Asian girl wearing a very modest white bikini, kneeling on a beach and facing the camera. The "quote" under the photo read: "Bold World Squad. You bet."

I rest my case.

I'll have to check the dip out. I think it falls off, but was not looking for that.
The driver tubes you talked about. Is that more than one driver tube or are there only three tubes in all?
With my antenna it could be very easily that, but it tune to 1.5. That's my weekend project for this week. I downloaded the op manual, but have not had time to do more than glance at it. Now I have two weekend project.
I off to www.mods.dk. http://www.mods.dk.
Thanks.

Hello to All & I hope this finds you well,

I don't know if this has been reported here or not but with such a lot of new members logging in lately I thought this might be of interest. I've seen a lot of commentary bemoaning the fact that there is no real active community of kits & kit builders/developers today accompanied by a lot of new folks who want to learn. There is a thriving community of such folk out there. One vendor is somewhat altruistically sponsoring a gathering point for doing this(they do after all hope to sell you the parts). I refer to Jameco Electronics who sponsors the Club-Jameco website. They co-ordinate and offer ideas, briefs, and actual, honest-to-God kits on the site. In example; Here is one of the projects from today's bulletin: a resistive decade load.
"You can use this 5W box as a high-power load for testing a circuit’s ability to drive resistive loads or as a variable resistor for circuit creation. It has a 1% accuracy from 0.1 ohm to 999.9 ohms, and can be set to any resistance in 0.1 ohm steps." Sounds very much like something Terry might recommend for a workbench.
I've got no horse in this race and no connection to Jameco other rhan as a satisfied small parts customer. I just thought I'd pass along the opportunity to give it a look-see. A greater Amateur presence in their community might bring a greater presence of these foks in ours. Everybody wins. Here's a link for your consideration.
http://www.clubjameco.com/index.php/contents http://www.clubjameco.com/index.php/contents
If you sign-up (join the club) you'll get occasional bulletins describing projects, contests, & interesting stuff. I hope this helps someone.
Vy 73,
Mike
K8SYN
P.S.
I believe Radio Shack is also entering in to this concept. I haven't checked them out so I can't offer comment on the effort.

So, turn the RF gain up, select (for example) 7MHz, stick it down the bottom of the band because you're sure to hear some CW about 7.003MHz, and as you sweep the drive control from one end ot the other you don't hear a change in the noise level?

I removed the mic head and tested. It is reacting with testing using a meter. I don't have a 'scope.

1. Check that one of the wires HAS continuity to pin 1 of the 4 pin plug.
Check
2. Check that the other wire HAS continuity to pin 4 of the 4 pin plug.
Check

3. Check that there is no short between the two wires in the mic head.
Check

4. While the meter is connected across the wires press the PTT. There should be no short.
Check

5. Check that there is NO continuity from EITHER wire to the case/stand.
Red wire has continuity.

6. Press the PTT and check that there is NO continuity from EITHER wire to the case/stand.
Red wire has continuity.

7. Check that there is NO continuity from EITHER wire to pin 3 of the 4 pin plug.
Red wire has continuity.

8. Press the PTT and verify NO continuity from EITHER wire to pin 3 of the 4 pin plug.
Red wire has continuity.

9. Check that there is NO continuity from EITHER wire to pin 2 of the 4 pin plug.
Check

10. Press the PTT and verify NO continuity from EITHER wire to pin 2 of the 4 pin plug.
Check

The red wire goes through some piece at the top of the handle where the red and white wires turn into black and green.. I took apart the head assembly and found that the red wire gets connectivity through the metal (painted black) piece that hold the wires. It conducts through the screw to the handle and then to the base.

Turning the drive control does change the noise level but not enough to easily hear even with the volume at 100%. We originally thought is was the AF board. However, when I push the WWV button the volume is pretty loud even with the knob around 25%.

What does the Marker signal do with JJY/WWV in OFF? Can you peak the S-meter with Drive control and if so what level do you get. Check with VFO at approx 200 on each band.

Do you have a lap top with a sound card, a tape recorder, a MP3, iPod etc. Anything with an audio output or headphones jack that you can input audio signal of any kind in to the mic line? Might have to go to Radio Shack and buy a patch cord.

If not then just load the rig normally in CW mode and turn off the Screen Grid switch and do this:

1. Place meter to ALC
2. Place mode to LSB or USB
3. Set Mic gain to approx 3:00 or 8
4. Take a alligator test lead or a piece of insulated hook-up wire with each end stripped.
5. Hold one alligator clip or bare end of hook-up wire between fingers of one hand
6. Flip to Send
7. Touch the other end of the jumper lead to the bottom right pin of the mic jack

As you touch or tap the jumper lead on the mic audio input pin you should get good ALC meter deflection. If meter deflects and stays deflected at the 8 setting of the mic gain pot without touching jumper to the pin then just turn the gain down until it returns to zero and repeat tapping the jumper on the pin. Each time you touch jumper to the pin you should get a good meter deflection.

Chad:

The mice were the least of your troubles. Sorry, your rig has had the "Golden Screwdriver" treatment, and you need to start from pretty much scratch getting it re-tuned and back into alignment.

I'm presently dealing with some of the same issues, specifically the CB conversion, which is that 28 MHz vice 10-meter business you mentioned. THAT is why I am sure some ham-handed hack has been in there with that golden screwdriver. We can HOPE they didn't ALSO try to "boost the power" by over-driving the finals.

A few days ago I posted specific instructions on replacing the crystals that were changed out. Apparently they were thought to be pretty good since no-one complained about my missing anything major. I will dig them back up and send them to your email directly rather than cluttering the list with it again.

You need to check the receive frequencies on all the 10-meter switch settings. Usually/So far as I have been able to find, they change the LAST TWO to cover 28 to 29 MHz, 600 KHz at a crack with some overlap and coverage above 29. If they only changed ONE of the crystals you need to know which one to replace, I'm going to bet it's both crystals, and you need to know which TWO of the three band switch settings are CB instead of 10M. That information gives you the crystals they changed.

You're going to be needing to get about $46.50-worth (shipped and all) of crystals cut and polished to bring it back to 10M from the 11M hack. The person you need to talk to is Sara Gore at International Crystal Manufacturing (ICM). Here is her contact information:
Sara Gore
800-725-1426x237
International Crystal MFG
10 N Lee
Oklahoma City, OK 73102
sarag@...

Tell her it's the same exact crystals that she just sent to me, order number was Q31875.

(If it's BOTH crystals, that is. If only one, you'll need to find the one by comparing the band-switch setting that has the CB frequencies to

the schematic of the oscillator board, and then pull only that crystal for replacement. The parts list for the radio in the service documents list the crystals by frequency; you just choose the one that was pulled, it's actually the simplest part of this whole mess.)

Once the replacements are made you will be going through the re-alignment steps in the manual. You're likely going to need to get help from someone local who has some tools. Of all the tools that you could get, at the VERY LEAST cabbage onto a VTVM, yes, one of those old boat-anchors with the great big swinging needle. They're fairly cheap at ham fests and even on auctions sites. You will likely need to build a probe or two, the RF one with three diodes is the most necessary (besides the straight-through stock one). Couple of bucks, or a junk-box trawl and an old Sharpie marker for the body. Piece of stray coax, and a brass nail for a probe point.

A VTVM is NECESSARY unless you have bajillion-bucks to get a modern high-input-impedance (10 or 11 MegOhm MINIMUM) fast-response digital meter. But the old swing-needle is still going to be better for most of this. We're not dealing in tenths or hundredths of a volt making a big difference, like some digital circuits. Mostly, if the meter swings at all, that's good enough for troubleshooting a lot of the time.

Do you have all the manuals, operating manual and service guide, downloaded? A high-resolution copy of the schematic, also. I've got a copy currently at Staples, being printed on their largest paper and then laminated in plastic. Dry-erase markers to scrawl on the plastic, makes chasing down circuits a little easier, particularly in "Large Print Edition" like this. My old eyes don't see so well any more.

Off the top of my head I don't know the wire to check for over-driving the finals. One wire will have been moved from the 210 post on the rectifier board to the 300 pin. Someone here (and there are a lot of those someones) smarter than I and / or has seen it already can tell you which to check. If it has been swapped, you will want to move it back to the 210 peg.

It's a stupid thing to have done but some of these idiots don't know what "logarithmic" means and think that adding a few volts to the finals makes a bit of difference on the receiving end. Doubling the power of course takes four times the input...

There are some of the things to check, and more will be handed to you as the questions get more specific and you know more. Study the circuits, including the descriptions in the operator's manual. Knowing what's going on helps figure out what to fix when it's not going. Best advice I know to give, there. These are really great radios, but they take some thinking, and a little TLC now and then. Good luck. I'll be posting those crystal-replacement directions shortly, directly to your email account.

The schematic shows switch S-21 between pins 3 and 5
on the remote vfo connector. It is not drawn with their usual
symbol for a relay contact, but rather as a N. C. slide switch.

I am guessing this switch is used to tell the 830S that a remote vfo is connected.

Can someone tell me where it is physically located?
What is its purpose.?

Thanks, Jim K8JL

Terry K9TW, I'll try to get back out there tonight and check that. It depends on my pain level.

Wes, WOW! Thanks for all of the info.
28 on the BAND switch is the one that was changed to 11M. According to the manual, it's 36.895MHz that I'll need to change back. Being stuck on disability makes affording anything REALLY difficult so I might have to leave it on 11M. If I ever do have enough money for the crystal, I'll call Sara.

My buddy has a VTVM and a freq. counter but we don't have a sweep generator to do the alignment. I've been trying to find someone local that might let me borrow one. No luck so far.

I do have the manual and the service manual and, thanks to this group, I have the manuals with voltages on them.

I'll check out the overdrive issue next time I can get out to the shack. Pain level is a bit too high right now.

I REALLY appreciate your time and the info. I'm saving that for future reference.

Larry,

You said:

"The ALC meter does work when receiving"

If I may ask, where did you get the idea there is a receive ALC meter?

If I may ask, do you know what ALC is and how it is used in the KW hybrids?

There is no such thing as a receive ALC meter.

Actually Jim, I agree with Joe and your comment:

"it's probably not worth the trouble"

You would be much better off looking for and obtaining either a VFO-520 or VFO-820 for your 820. Yes, a VFO-520 will work, plug and play, with a TS-820/TS-820S and vice verse, a VFO-820 will work plug and play with a TS-520/TS-520S/TS-520SE.

Chad

Not sure why you think you need a Sweep Generator? Only place you need that for is checking and aligning the Rx and TX bandpass filters (BPF) and I would not worry about them at this point. Typically after a CB hack you can replace the Het Osc crystals that were swapped out and then perform the Coil Pack alignment that is detailed under the Maintenance Section of your Owners Operating Instruction Manual. Not likely that they messed with the BPFs. They may or may not have messed with the 10 meter Ant, Mixer and Drive coils after the crystal change out.

You will use the Marker as your standard RF signal generator and the S meter as your RF measuring indicator.

Study the procedure and do in proper sequence and you Must use proper alignment tool. Must inspect all the coil slugs to make sure none cracked before you proceed. Also look at the cardboard formers and make sure none are ripped off the PC boards. If encounter a stuck core do not force it. Can apply small amount of WD-40 with a point of toothpick at top edge of the core to former interface to see if that frees the core. If not can apply small tip of hot soldering iron to the core very briefly.

Again not sure why you are wanting a Sweep Generator at this point?? It is not a troubleshooting instrument. If you have low S meter indication on any band after doing the coil pack alignment then come back for additional help.

Terry K9TW

48164. TS-830S ALC/Drive levels

Yahoo group: TS-520_820_530_830 (2014)

Topic: 48164 Message: 48164

Two questions about Drive and ALC metering on the hybrids (or at least the 530/830):

1. Do VR6 and VR7 on the IF board actually regulate the threshold and maximum ALC levels or merely the metering of them?

2. Is it normal for the Drive level -- as indicated by the ALC meter scale -- to vary from one end of a given band to another? (And to vary signficantly from one band to another).

Curiously,
Craig
W3CRR

Hi Guys,

briefly:) first question regarding DFC-230 and it's use in TS-530S and TS-830S
went unanswered:(

Here is another one:)

I have several Cw filters mainly YK-88C-1 and YG-455C-1 and YG-455CN-1 laying around.
Would like to use them in TS-530SP and TS-830S.

Reffereing to both service manuals, could i simply change carrier frequency oscillator for cw in trcvx
in order to meet central frequencies of filters in question? i.e.: if said carrier oscilator 8831,7 kHz
for Cw filter with center frequency 8830,7 In my case where cw filter has central frequency 8830,
could i move carrier oscillator to 8830,7 ??
(Or at such a value frequency wise, that i could still has beat tone using IF shift in both cases?)
Main frequency of carrier oscillator could be changed by couple of hundreds Hertz up or down,
right??

Thanks for space,

Nermin S58DX

I just use that term ALC to refer to the meter on the rig as opposed to the meter on the voltmeter.
I'm sure I'm not be using the terminology correctly. Don't get caught up in that. It doesn't help.

Larry,

Good work. You need to insulate that RED wire since your test results indicate it is connected to frame ground (pin 3 on the 4 pin plug) and is grounding one side of the mic element. Once you have it insulated repeat all of the tests. I say "all" tests because that will verify your corrective action as well as assure you that you didn't introduce any new issues (it happens!).

You are making progress - hang in there!

VR6 and VR7 have nothing to do with the ALC bus voltage other than monitoring it. They are the zero and span adjustments for a reverse reading high impedance FET based voltmeter.

Look at Q30 and you will see it is a FET. Its Gate is hanging on the ALC bus. This bus is very high impedance power supply and cannot support any load current. Is just a dc control voltage that feeds Gate 2 of the TIF amp. A FET is used as its Gate offers very high input impedance so the ALC bus doesnt know it is there. If Q30 fails it will pull the bus down and your RF drive from the TIF amp will be reduced. Rare but it does happen same as Q11 for AGC bus.

ALC threshold is a function of the difference between the positive peak of the RF drive envelope and where the 6146 control grid operating bias negative dc voltage is set at (you set that when you set the zero signal resting plate current). Some set this to 50 ma and other to 60ma which varies the offset voltage level). The higher the RF drive envelope is compared to this dc offset voltage the lower the ALC bus voltage will go and the higher the meter will deflect. The lower the peak RF drive envelope to the dc offset voltage the higher the ALC bus remains and less meter deflection. It is a function of how much grid current flows in the FG line and how hard Q19 is turned on. Higher rf voltage on the positive peak means grid more positive with respect to the cathode and more grid current.

For example if the control grids bias voltage has been set for -60vdc then you will need approx 42.5 rms rf drive volts to just start to see any ALC indication. 42.5 x 1.414 = 60.1 peak rf volts. 60.1 - 60 = .10vdc delta. The control grid is now 0.10vdc positive with respect to the cathode.

Any RF drive voltage less than 42.5 rms or 60.1 peak rf volts means no grid current which means no ALC action or indication. Will still have RF output on the wattmeter just no ALC indication. Normal RF drive varies from band to band typically ranging from approx 46 to 49 rms rf volts. This should give you max ALC indication as you have max grid current (approx 45ua).

Once you go above approx 42.5 rms rf drive volts the 6146 control grid is know positive with respect to the cathode and grid current starts to flow (very very low ua grid current with a max of approx 45ua). When this ua grid current flows Q19 the ALC amp transistor (it is configured as a dynamic zener diode) on the Audio board is biased on and provides a very small negative voltage at its Collector (approx -1.0vdc) that bucks or series opposes the +3.6vdc RF-1 voltage on the bus lowering the bus and reducing the control voltage to the TIF amp Q29.

I will let someone else respond to question number 2.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <crgrbrts@...> wrote :

Two questions about Drive and ALC metering on the hybrids (or at least the 530/830):

1. Do VR6 and VR7 on the IF board actually regulate the threshold and maximum ALC levels or merely the metering of them?

2. Is it normal for the Drive level -- as indicated by the ALC meter scale -- to vary from one end of a given band to another? (And to vary signficantly from one band to another).

Curiously,

Topic: 48164 Message: 48171

Craig:

Really helps to graph it to see it, but I cant do that with this medium. Make yourself a graph with a Y axis that swings positive and negative (up and down) either side of the X-axis (normal zero) and place a dotted line on the Y axis at -60vdc and extend it from left to right. This is where your 6146 control grids are sitting with respect to the cathode. All you really need is Quadrant 1 and 4 (upper right and lower right) .

Now draw one cycle of the approx 138vac P-P RF drive envelope (49rms X 2.828).Start at zero degrees on the -60 dotted line axis and draw positive peak crossing the X-axis and peaking at + 9 at 90 degrees and then back down thru zero crossing at -60 dotted line at 180 degrees and end the negative peak at -129 at 270 degrees and bring it back to -60 at 360 degrees. Now you can see one complete RF cycle and will note very few degrees of the positive going drive envelope is above X axis or Zero. You can see that the drive envelope has to swing above Zero X-axis for the control grid to become Positive with respect to the Cathode and to do that it has to overcome this negative dc offset that the operating bias presents. So you will have pulses of RF drive that cause grid current to flow. Remember these pulses are at RF at a mhz rate ie 14.2mhz. Also, in SSB mode this approx 45ua grid current is essentially varying at an audio rate.

Also, I forgot to mention to you that the RF drive voltage I gave you in response to question 1 is for 20 meters at approx 200 on the VFO (TX Level Diagram). 49 rms rf volts drive is about max for a TS830.

That should help you figure out part of your No 2 question which is really two questions with one answer being No and one being Yes!

My friend and I were going to do a complete alignment since this radio seems to have been abused by the previous owner. I don't know if it's a factory thing but nearly all of the cans have a black line on them. I'm assuming that's where the groove was pointing. There are quite a few that don't line up with the marks. I figured this definitely meant someone had been in there tinkering. The first step in the alignment calls for a sweep generator.

48174. DDS VFO 530 830 Update part 2 3/14/2014

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-14 21:27:51 UTC
From: <cocobean64@...>
Topic: 48174 Message: 48174

Hello Everyone,

For those interested, here is another update.
I've made some changes from the original concept.

The Arduino Uno in the radio, has been replaced with an Arduino Mega.
The extra I/O capabilities of the Mega now allow for the oscillator to be mounted in the radio.
There will only be three wires required to communicate between the internal Arduino and the external Arduino, no other connections are needed between "Radio" and "External VFO". This simplifies the set-up.

You can run the radio without having the external VFO powered up. The Arduino in the radio senses that the external unit is off and automatically will select the original internal analog VFO in the radio.
Similarly, if you power up the external VFO, it is sensed automatically and the DDS VFO will be selected.

Its been a lot of work, and boatloads of fun to "tinker with" and make it work. Still need the finishing touches, but its sooooo close...LOL
Going to try it on the air tonight.....

Attachments are not allowed here so I will put the link in here to the latest video. My apologies for the quality this time.

A little further information - the HV meter reads 900 volts so a little higher than the 800 given in the manual.
I've had a look for any obvious blown components - particularly capacitors and all appeared OK with no signs of bulging -The HV caps "appear" in normal state & given the above they would appear to be functional.
I swapped another driver tube in with no changes noted. I removed the finals and to my uneducated eye they were intact. The filaments both glowed with heater on and responded to the heater switch.
There was a ceramic cap in the final cage that didn't look great which goes from the choke to the plate variable capacitor. The fan in the PA is functional. The tube closer to the rear of radio does not illuminate as much as the "front" tube.
Not scientific but eliminating the clearly obvious is a start.
What to check next ? with just a multi meter to work with!

Christopher:

Just to be sure this got through, and to make certain that things like "900 VDC" actually sank in to your conscious mind, you DO in fact realize that the voltages and currents in that part of the rig can

KILL YOU.

As in "dead," "silent key."

From here, we can't tell who knows how to what, so I just want to be sure this got in there. Nobody wants to hear that your rig is being auctioned after the funeral, OK? NOT being insulting or snide here, just seen too many people hurt working on high potentials (from back in the tube telly days, as well as ham gear).

As to using a plain-vanilla FET or transistor multimeter, with at BEST a one-megohm input impedance, the act of putting it in the circuits you're dealing with here will more than likely load the thing down to the point it won't function any longer at all. (And come back up when you pull the meter, so likely no real harm done.) And the reading will be WAY off of what the actual voltages are when the thing is operating.

THAT is why the whole push to getting everyone with a hybrid or straight-tube rig equipped with a vacuum-tube (valve) voltmeter. They have input impedances in the 10 to 11 megohm ranges, and that quantum difference makes them usable in this kind of environment.

That is true that after setting the 9vdc regulated and the RF-1 voltages the Service Manual calls for aligning the Rx and Tx bandpass filters. A sweep gen and detector and regular RF sig gen to input the KW markers is needed for this. The coils all interact and takes a little experience to align them. Also the response curve will not typically be the nice artist rendition that is in the manual.

Can find out where BPFs are at with a regular RF sig gen and stepping thru from approx 8 mhz to 9.5 mhz in 100khz steps and smaller steps as you near Fc and measuring and recording the RF output voltage and then plotting the points on graph paper or excel. A bit tedious and not good for adjusting, but will tell you if they have been messed with.

It is possible that previous owner has messed with all the IF and RF transformers. I would ignore all the black marks on top of the cans. You could align every core slot to those marks, but at how many turns? The marks are typically useless.

The very first thing you should do is use the Marker signal to see what your S meter indication is on each band. Should be very close to S8 to S9 on all bands except 10 meters if the receiver is in fully functional and in good state of trim. I would concentrate on the receiver first.

The easiest way to peak up the Rx performance is to use the Marker signal and panel meter and perform the abbreviated alignment in Sect 6 Maintenance of your Operating Manual. In about 30 minutes can have rig in very good state of tune assuming no failures or degraded state. People call this doing the Coil Pack alignment even though you will also do some of the IFTs. You will notice they caution here not to touch the BPF coils.

Only thing you cannot do precisely is calibrate the S-meter, but can get it close by doing the Coil Pack alignment and then on 20 meters at 14.2 mhz adjust the span control VR-2 for an S9 indication. This is good enough for what an S-meter should be used for. Need a good RF sig gen to input -73dBm (50uv) for more accurate cal, but as I said using the Marker gets you close. An S-meters real value is for making comparisons ie barefoot vs linear or dipole vs beam or beam front to back. Some folks crank VR-2 up so they dont have to make excuses for a scotch S meter. They like to see it dance. It has no effect on the receiver sensitivity.

I am trying to tell you how in very short amount of time with no test gear other than rigs Marker as a sig gen and the S-meter as rf detector you can get the rig operating very well. After proving it is functional can then always perform the full service manual alignment but not something for inexperienced person to take on and not a troubleshooting or routine evolution.

Of course your rig and free to do whatever you want.

Have fun and be careful around the lethal voltages.

Christopher,

I don't understand what you are actually saying. You first said the HV meter indicated "900VDC" which you said was higher than the 800VDC stated in the manual. You then said the HV meter pegged fully to the right. You are saying to different things about the HV meter. The HV meter switch position only works when the 520 transmitter is keyed.

Are you sure you are looking at the meter correctly?

Wes - I understand the HV the PA can still contain is lethal. After waiting 5 minute from power off with leads removed, I ground the top of the choke for 10 seconds, then do it again. In the files section there is a image of exactly what to do so I think I'm taking the required precautions.

Q "Sorry, forgot to ask the other question. About the capacitor and coilinside the PA cage, and it looking "bad." Describe "bad" please? Burnt? Browned? Charred? Sort of leaking a waxy kind of substance
perhaps?"
A: This is a hefty ceramic cap - it is not burnt, charred or brown but is breaking away from the legs. I do have a final cage replacement kit from hybrid restore

Q" How about the state of the coil? Is it sort of dark-brown, and looks as if it has been subjected to intense heat by any chance?
A The windings on the chock are still light bright colour - not brown

I made this clip for a close up of the PA & other main caps

Christopher,

My first thought is the bias pot may be very dirty causing loss of final tube grid bias voltage. The other possibility is the bias supply, -C on the Rectifier Unit, has failed.

Remove all power, wait for the caps to discharge (use a DC volt meter to verify the caps have discharged), then clean the bias pot with contact cleaner. Use canned air or compressed air to remove all cleaner residue. This cleaning process requires removing the top and bottom cabinet covers and turning the 520 on it's maintenance side (see the 520 manual for details on the maintenance position).

Connect a DC volt meter (set to measure 500VDC or more) to pin 5 of the 520 6146 final tube socket, it doesn't matter which socket since both 6146 grid pins are wired in parallel. Set the SG switch to OFF, and power up the 520. The grid voltage should be approximate -100VDC or so in receive. Set the Mode switch to SSB (USB or LSB, it doesn't matter) then key the transmitter (use the SEND key). The grid voltage should drop to approximate -65VDC. Unkey the transmitter. If the grid voltage drops to -65VDC or so with the transmitter keyed then power the 520 OFF, set the SG switch to ON, and put the cabinet cover back on and test for proper operation.

If the above test results in final tube socket pin 5 grid voltage at "0VDC", check the bias supply, -C, on the Rectifier Unit, it's possible it's failed, shorted capacitor taking out the bias supply diode.

Some time the bias pot can get a dirty spot on the resistive element causing loss of connection from the wiper to the resistive element. This will result in loss of bias voltage to the final tubes causing the IP meter to peg fully to the right and the final tubes conducting to saturation. Cleaning the bias pot quite often eliminates this problem but some times the bias supply can fail causing the same symptoms, 6146's conducting to saturation levels (IP pegs fully to the right in transmit).

You can set the SG switch to OFF and measure the 6146 grid voltage with the transmitter keyed. Setting the SG switch to OFF will prevent the 6146s from conducting and you can measure the 6146 grid voltage (pin 5 on the 6146 socket) while adjusting the bias pot to ensure the bias voltage varies up and down in a smooth manner. If cleaning the bias pot fixed the loss of grid bias to the final tubes then button the 520 up and perform the final tube 60ma idling current adjustment outlined in the 520 operator's manual.

Christopher:

Just to be sure this got through, and to make certain that things like "900 VDC" actually sank in to your conscious mind, you DO in fact realize that the voltages and currents in that part of the rig can

KILL YOU.

As in "dead," "silent key."

From here, we can't tell who knows how to what, so I just want to be sure this got in there. Nobody wants to hear that your rig is being auctioned after the funeral, OK? NOT being insulting or snide here, just seen too many people hurt working on high potentials (from back in the tube telly days, as well as ham gear).

As to using a plain-vanilla FET or transistor multimeter, with at BEST a one-megohm input impedance, the act of putting it in the circuits you're dealing with here will more than likely load the thing down to the point it won't function any longer at all. (And come back up when you pull the meter, so likely no real harm done.) And the reading will be WAY off of what the actual voltages are when the thing is operating.

THAT is why the whole push to getting everyone with a hybrid or straight-tube rig equipped with a vacuum-tube (valve) voltmeter. They have input impedances in the 10 to 11 megohm ranges, and that quantum difference makes them usable in this kind of environment.

OK not much to do RIGHT.

Simply set the VFO to around 250, AGC to Slow, meter switch to ALC, Drive control at 1200, Function Switch to 25khz or CAL position, tune the VFO to find and peak the 25khz cal signal on the S-meter indication, adjust the Drive control to peak the S-meter reading.

Marker signal should never peg the S-meter on any band. Typically would see S8 to S9 on most bands and lower on 10 meters maybe S5 to S7.

Terry

Have given the Bias pot on the side panel a good spray with contact cleaner - key down in IP meter still pegs instantly across. Turning the bias adjustment pot made no difference at all to needle indication Turned SG switch to OFF and attempted to measure VDC on PIN 5 of socket with tube removed. It is not easy to find a PIN diagram for the 6146 socket but from what I did find indicated pin 5 is to the immediate right of the positioning notch. ie about 1 oclock position. Found zero output from this pin. I checked other pins also and most measured zero with a couple actually going backwards? Still not certain I;ve taken this measurement correctly. If I have then next step would be as per Mikes suggestion; If the above test results in final tube socket pin 5 grid voltage at;0VDC, check the bias supply, -C, on the Rectifier Unit, its possible its failed, shorted capacitor taking out the bias supply diode.

What should bias supply measure? If simply a VDC, I should be able to test with my simple multimeter.

Thanks for suggestions thus far, it's an education!

Christopher,

It does appear the bias supply on the Rectifier Unit, -C terminal, has failed.

You should keep the SG switch in the OFF position, this will result in "0VDC" applied to the final tube screens which will prevent electron flow in the final tubes. With 0VDC on the final tube screens, the final tube screens will appear "negative" in respect to the cathode which will "repel" electrons that flow towards the screen and plate, back to the cathode, hence preventing electron flow in the final tubes.

If you left the SG switch in the "ON" position then the normal positive screen voltage will be applied to the final tube screens and with loss of grid bias voltage to the final tubes(failure in the Rectifier Unit's -C supply), the final tubes will conduct fully, to saturation levels, "even in receive", and you don't want that to happen while you are checking the -C bias supply! Why would the final tubes conduct fully in receive? It's simple, loss of bias voltage due to failure in the -C bias supply, will cause the grids of the final tubes to be 0VDC allowing current to flow in the final tubes, even in receive!

I forgot to mention, the -C terminal on the Rectifier Unit (Bias supply) should be approximately -110VDC or so. Notice that's a "negative" voltage so you will have to set your DC volt meter to measure a "negative" voltage.

Mike,
I'll check this out with my scope, but I think the screen on/off switch, applies some -C (through a 100k resistor) in the off position (check out the schematic to verify this for me). So I would think the screen has a very high negative potential in off position?

Yes, Jan, that's right "IF" the bias supply, -C, is working. However, based on Christopher's initial voltage checks at the grid of the final tubes, pin 5, and cleaning of the bias pot, the final tube grid bias voltage is 0VDC which could indicate the Rectifier Unit's -C bias supply has failed.

Normally, when the -C bias supply is working properly, placing the SG switch to the OFF position would, in fact, apply a "negative" voltage "from" the -C supply. However, if Christopher's -C supply is, in fact, bad then placing the SG switch to the OFF position would result in 0VDC being applied to the final tube screens. This would prevent the final tubes from conducting in transmit and receive.

As I said, if the 6146 screen voltage is 0VDC then the screens will be negative in respects to the cathode which would prevent any electrons from flowing up to and past the screens to the plate, hence no current flow in the final tubes.

When Christopher is measuring/check the -C supply, you don't want any current to flow in the final tube if, in fact, the -C supply has failed so that's why I told Christopher to put the SG switch in the OFF position.

Pin 5 is not adjacent to the locator tab.

Pin 1 and 8 will be on each side of locator tab. Pin 5 will be at approx 1100 viewed from the bottom. Octal socket numbering convention is to view socket from the bottom and count in CCW direction from the tab from 1 to 8. On most phenolic sockets the numbers are embossed on them at each pin location. Also easy to see Pin 5 as it has the parastic suppressors.

Easy to get turned around if viewing from the top.

Is the Send/Receive switch in Receive? Is the Heater switch OFF?

For now until you get this radio working in Receive mode I would make sure before you turn the Power switch on that these two switches are in the above noted positions. In this way rig wont be keyed and wont have finals run away on power on.

If the rig is in Receive mode and you are saying that the S meter pegged full scale when you powered on and is not coming back down to zero and it is remaining at or near full scale deflection it sounds like the AGC bus that it monitors is not powered or is very low. Could be dirty RL-1 aux relay contact.

Topic: 48194 Message: 48197

We pulled the antenna relay and and the two larger connectors are only getting 0.024 volts with the radio on. I'm guessing that means there's no power to the relay. Am I correct or does something else (the SEND switch) trigger that relay?

I'm not touching the SEND switch until I figure out what's up with the meter maxed out.

Another thing we found is two pots on the FIX board are broken. Again, am I correct in thinking that that's a separate issue?

I can't tell you how much I appreciate ALL of your help!!!

There is no such thing as a VOX relay.

The relay keying transistor is on the VOX board. The Aux or TR relay is on top the radio under the VOX board on the left rear of the rig.

This relay performs auxiliary functions like switching the cutoff and operating bias on the finals and the driver tube and receiver transmit and receive bias voltages and the AGC and ALC bus metering functions.

The Ant relay is on bottom side at end of bandswitch shaft under a metal shield cover. They are identical relays and get 12vdc operating voltage when the switching transistor on the VOX board makes the RL line hot.This is done by grounding the SS terminal with the mic PTT or the Send switch or with audio input to the VOX board in VOX mode.

There is no voltage to the ANT relay with rig turned on in receive mode.

You want the relay actuating coil de-energized as the receive signal is applied thru the NC (normally closed) contacts of the relay. The NO (Normally Open) contacts close when relay is keyed to allow transmit RF output power to be applied to the SO-239 connector and to your dummy load.

No disrepect to you friend but it appears he does not have the experience level that you need.

Look at the schematic. Look at the IF board. At lower left corner you will see the meter driver circuit. Just left of the meter FET Q7 and off the IF board you will see relay contacts drawn. RL1-1 is a NC contact of the Aux relay mounted under the Vox board. The AGC bus supply voltage from RF-1 is supplied by this contact to provide the control voltage for Q1 RF amp and the gate of the meter FET Q7 which monitors this voltage. If this NC contact is dirty then you will have no or low AGC bus voltage causing the S-meter to stay pegged.

You can also measure RF-1 at the AVR board to make sure it is close to 3.2 vdc and while there make sure you have regulated 9vdc. These are two key voltages for the receiver.

Ken -
This is getting really frustrating.
As I'm close to getting everything together, the switch assembly in the handle drops out. Looking in the handle, I don't see how the switch even stayed in place. There is nothing to hold it to the external switch.
It decided to try just hooking up the switch assembly directly to the pin 2 and 3 wires and the pin 1 and 4 wires directly to the mic, as shown in the manual. That doesn't work either. At least I don't think it does. When I hit the switch, I hear a tick in the rig like something is switching. That's a new sound. I still hear incoming sound. Speaking does nothing on the meter, which is still in receive mode.

I have now tested PIN 5 DC Voltage as per Mike's suggestion. Note my old meter won't measure negative values so I had to switch probes around- and start looking at buying a modern meter!

SG switch turned to OFF position and 1 tube removed to perform test . access the socket
The DC voltage in RX could be adjusted using the bias pot on the side panel but it was right about 100 VDC before I touched anything. When I went to SB TX it sat about 68 VDC so appears to be right where it should be.
After replacing the tube and SG switch to on I tested TX and as before, with meter in IP, the needle pegs to the right and adjusting the bias pot made no difference at all.
Here is a clip made of the test
https://www.youtube.com/watch?v=LzdMNtUC-hk&feature=youtu.be
https://www.youtube.com/watch?v=LzdMNtUC-hk&feature=youtu.be
Firstly- have I done the test correctly? Secondly if so , what should be looked at next?
Thanks for the help so far

Christopher,

You initially said you measured the bias voltage at pin 5 of the 6146 tube sockets with both 6146 tubes in their sockets and the bias voltage at pin 5 measured 0VDC.

You then said you removed one of the 6146s and measured pin 5 from the top of the empty 6146 tube socket and the grid voltage on pin 5 was -100VDC in receive then dropping to -65VDC with the transmitter keyed and the bias voltage varied when you adjusted the bias pot. That's a good sign.

You then said you put the 6146 back into the socket, set the meter switch to IP, and keyed the transmitter which resulted in the IP meter pegged fully to the right. That is NOT a good sign!

If this is right, I question the 6146 tubes in your 520, one may have a short in the tube which is causing the tube to conduct fully, pegging the IP meter fully to the right.

If you have a pair of know good 6146s, remove the 6146 tubes in your 520 and put the 2 known good 6146s and repeat the test to see if the IP meter pegs.

As Terry said, pin 5 on the 520 final amp PC board has the parasitic suppressors connected to them. A parasitic suppressor is a resistor with wire wrapped around the resistor. There is one parasitic suppressor connected to each pin 5. I should have told you that in the beginning but now you know so measure the grid voltage at the PC board connection of either one of the pin 5 grid parasitic suppressors, it doesn't matter which one the grids are wired in "parallel" and they both will have the same bias voltage.

Tom and others,

This has been a topic of discussion at great lengths many many times in the past.

If you and other member want to discuss whether Heathkit will rise again or not, take the discussion off group through private email.

Thank you and 73

From: Ken Winterling
Topic: 48031 Message: 48206

Larry,

I would have to take a G stand apart to help you with the assembly details since I can't recall that from memory. Hopefully somebody here will be able to help with that. I will not be able to do it today.

As for the mic wiring, lets test the PTT circuit in the rig first to eliminate it a contributing problem. IIRC, when viewing the 4 pin mic jack on the rig's front panel the index "bump" is at the 6 o'clock position. That roughly puts pin 1 at 5 o'clock, pin 4 at 7 o'clock, pin 3 at 11 o'clock, and pin 2 at 2 o'clock.

OK, turn on the rig in receive mode. If you can hear stations that is OK but if not just turn up the volume a bit so you hear noise from the speaker. I'm working on a number of issues so I don't recall if you said you have another mic that works on the rig. If you have a known-good mic then plug it in and press the PTT switch. If the rig switches to transmit mode and you do not hear stations or noise then the PTT circuit is working. If this does not work or you do not have a good mic then proceed with the test below.

Take a jumper clip test lead and connect one end to chassis ground. You can clip it to the threaded ring on the mic jack but be sure it isn't shorting to any pins. Next, touch the free end of the jumper lead to pin 2 (2 o'clock) (PTT) and the rig should go into transmit mode and you should not hear stations or noise. Does that test work as expected? If that does not work then you have to investigate the PTT circuit.

Please report your findings.

Didnt want to step on your thread. I needed break from the bench and I thought I read that he was trying to measure cutoff and operating bias at Pins 1 and 8 either side of the locator key and didnt see anyone pick up on that so thought I better say something to him about octal tube socket numbering convention.

Sad when you take a break from working on KW hybrids to reading about troubleshooting them!

No problem Terry, that's why my response was formed somewhat into a question and a comment about what he Christopher was saying.

Pin 5, the grid #1, on the Final Unit 6146 tube socket is not difficult to find. As you said, and I agree, on each 6146 tube socket has the grid #1 parasitic suppressors connected to pin 5. Simply locate them on the bottom of the chassis either connected to the 6146 Final Unit 8 pin octal sockets mounted to the chassis or on the 6146 Final Unit PC board.

Terry
I was away for the week, but finally got back to my TS830 delayed receive sensitivity problem. After confirming that the problem had not magically gone away in my absence, I started making the voltage measurements as you suggested. The voltage recovery and the receive recovery were very quick. Apparently, wiggling the wires on connectors 3 and 8 (as you included in your suggestion) resolved the problem. ...at least for now. If the problem returns, at least I know where to look. Maybe I would be working better if my wires were wiggled at the 30+ year mark. Thanks again. Al Wolf, K2QU.

As for the VOX relay, I was just going by the service manual. Page 7 FIG 68. "Replacing the VOX relay". I'll pull that relay today and swap the two and see if that changes anything.

As for my friend, I know, but he's all I've got and he knows more than I do. :(

I hate it when things break/die just sitting overnight. LOL I'll get out there later this morning when it warms up a bit. I'll let ya know how it goes.

Does anyone out there need a website? If I can't get this going soon, I may need someone that will trade me the work for a website. I have NO money but I can barter with that. :/

Ok Chad I stand corrected. I see now why you called it the "VOX" relay. I can tell you among hybrid owners and hybrid service folks it would not commonly be called by that name.

Lots of things in the various Service Manuals that are not technically correct and some grossly wrong. I am very happy that you are trying to use the manual.

Not uncommon for these radios to exhibit intermittent conditions both transmit and receive. In the case of the TS520 you do not have molex connectors for the board interconnects but you do have relay contacts and switches and pots that can all exhibit intermittent conditions. Sometimes a good contact and sometimes not.

Relay swap is OK. Can also clean by wetting some printer paper strips with Deoxit or favorite contact cleaner and pulling thru the contacts (both the NO and NC contacts) and applying light pressure to the armature (movable piece). Should see black streaks appear on the paper. Dont attempt to bend the contacts or adjust them in any manner.

If relay swap or cleaning contacts doesnt help then measure RF-1 and 9vdc regulated at AVR board.

From: <wagstw46@...>
Topic: 48043 Message: 48213

Alan:

You can carefully remove the molex plugs and can apply small amount of Deoxit with tip of a pointed tooth pick.

If the plug and connector body move any amount side to side likely the soldering at the pin pad is the issue. Dont typically see this too much on the RF boards.

The IF board is typically the place that this is manifested the most because this board is pulled frequently to remove and sell filters or change filters. Frequent pulling of the molex connectors and applying side force to the connector body rocking it side to side as you pull upwards can break the solder and worse case can crack the pc pad trace. Soldering on these pins can be poor. Sometimes will find a complete 360 degree crack around the solder filet 'weld" with the pin floating.

If problem returns you may be in to pulling the RF board and inspecting all the molex pins under magnification.

Thanks for letting us know the status.

48215. Finished the DDS VFO on the 530

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-16 22:16:50 UTC
From: <cocobean64@...>
Topic: 48215 Message: 48215

Hello Everyone,

I've finished the DDS VFO with the TS-530. Posted some pictures on the site here, look for the "DDS VFO 530 finished" album.
Requirements of the project:
- I did not want to cut any wires, or drill any holes in the transceiver if possible.....done.
- The DDS VFO should interface with NaP3 via USB connection to a pc.....done.
- The DDS VFO to have, split, rit, xit, A to B to A transfer....done
- The DDS VFO to retain VFO-A and B frequencies and Rit/Xit settings upon power down.....done.
- The connection from the Transceiver to the DDS VFO should be simple.....done.

- The case to be similar in size (height) to the transceiver.....done. (needs paint?)

Connections between transceiver and DDS VFO:
- One 1/8 stereo audio cable runs between the DDS VFO and the transceiver, nothing else.
- One USB cable from the DDS VFO to the PC.
- One 12V wall wart to power the DDS VFO.
- Once RCA jack on the back of the transceiver for the IF out connection to the LP-Pan 2 (in an existing hole!)

Costs:
Parts were primarily sourced from flea-bay, and some from mouser. When I add it all up, this "first-off" is just shy of $400 in parts only. Compared to "used 230 or 240" vfo's this is high, but then this DDS VFO has more capabilities.

Summary:
This does require you to get into the transceiver and "pick-up" signals for band position, mode, and some others in order to get it all to play nice.
Some may not want to go this route as they like to keep the transceiver "all original".

Going forward:
Time to play with this for a while, but I'm already "thinking" of adding "memory buttons" and a keypad for "direct frequency entry". We'll have to see how this goes.

Comments or suggestions are welcome, send them to cocobean64@gmail.com.

This may sound really silly, but have you checked the RF gain control is fully clockwise?. When I first got my TS520S in 1979, I read the manual and went thru the steps in the Getting started section and misread the setting of the rf gain control and had it set fully CCW. on turn on the s meter went full scale. It took me about 3 attempts before I figured it out.

Very good suggestion. Simplest first. I failed to think of that as getting too familiar with how to operate these radios. Never would think anyone would ever set the RF gain full CCW. Even if you operate with the AGC off and ride the RF gain pot (which is a perfectly acceptable way to copy) cant imagine why you would put it at full CCW and leave it there? Lets hope you are correct.

Hi Bart,

Excellent job. I see you've thought quite a lot
about how the VFO will integrate into a working
system. The use of two micros makes a lot of
sense. It also looks like you could build the
unit inside a surplus VFO cabinet.

Have you listened for birdies etc due to the
integration of the Arduino board inside the
radio. Also, how clean is the VFO signal compared
to the internal VFO? It's probably difficult to
do phase noise measurements but can you listen to
the close in noise of a carrier using the
internal VFO and compare it to the external VFO?
Alternately, can you listen to a dog pile and
switch between internal and external VFO?

Topic: 48215 Message: 48219

Lou,

I cannot hear any birdies, but then my hearing is probably not the greatest either.
A phase noise measurement I cannot make, don't have the equipment for that. I did look at the DDS signal vs the analog and other then amplitude (dds slightly higher), the signal looks clean.
The AD9850 I'm using is "good" to 40Mhz so is claimed, although its also stated that there will be distortion at that level. I'm only going from ~5 to 6 Mhz (mimicking the analog range).
I can switching between internal and external vfo, is done automatically. If the internal (in the radio) Arduino senses a loss of communication from the main unit, it defaults back automatically to the analog vfo.

I've been playing on the air with it for a bit. The receiving ops are not reporting anything but clean audio and spot-on frequency.

Question, how do I listen to the "close in noise" of the carrier?

Here's a link to the final video.....

Terry
Thanks for the instructions. I won't fix anything till it really breaks - but again, you have given me the path forward when I need it. Except for a few electrolytics, relays, and cathode resistors, the primary issues I have had with the 830s are "mechanical" (loose connections, oxidation, loose grounds, broken traces, etc.). DeOxit, rubbing alcohol, canned air, and cleaning swabs (small brush) are the primary tools! Al Wolf, K2QU

Hi Bart,

First of all, to anyone that is reading I am NOT talking down the VFO.

This is a really excellent project and from what
I can hear and see from the videos anyone would
be proud to own one. My experience with digital
synthesis is that it is different from a signal
derived by traditional analog means. You can
always measure that difference with the right gear and the right tests.

To me, it's more important to LISTEN to the
signals and if it sounds ok then the numbers don't matter.

It's a good sign that you can't hear any birdies.
The phase noise measurements are difficult and in
the HF band probably more so especially when you
have an antenna connected. The phase noise from
AD9850 should be pretty low anyway and is quoted
at -134dBc @ 1kHz for a 5MHz signal - an
excellent figure. If you listen in close (less
than 1kHz) to a clean carrier you might hear all
kinds of swishes and little carriers from a
synthesised VFO. Depending on the signal
generation you might hear these signals all the
way out (some kHz) from your desired signal.
These come from digital noise produced by the signal synthesis process.

Also, depending on the cleanliness (maybe I
should say dirtyness?) of the synthesised signals
you might hear mixing products from strong
signals that are inside the RX filter passband.
That's why I asked you to listen to a pile up -
there's always a couple of really strong signals
in there that might make listening difficult.
What you would hear is an increase in noise
around the signals you are listening to. If you
switch between internal and external VFO and
can't hear the difference then the test is
completed. You "might" hear some increase in
noise but if it's not objectionable and you don't
think small signals are being obscured then there's nothing to worry about.

So the point of the test is to listen "around"
your desired signal especially in the presence of
strong nearby signals and check for unwanted

mixing products due to phase noise. It is very
rare that you would hear poor signals when you are on frequency.

It's a great project Bart, I'd be interested to read more about it.

You initially said you measured the bias voltage at pin 5 of the 6146 tube sockets with both 6146 tubes in their sockets and the bias voltage at pin 5 measured 0VDC.
I was not measuring the right pin and I didn't realise the figure given was a negative value! I took the minus sign as a hyphen! It took considerable time to find a pin /socket diagram showing top & bottom views. I did learn my multimeter wont show negative values unless I reverse the probes.
You then said you removed one of the 6146s and measured pin 5 from the top of the empty 6146 tube socket and the grid voltage on pin 5 was -100VDC in receive then dropping to -65VDC with the transmitter keyed and the bias voltage varied when you adjusted the bias pot. That's a good sign.
This is what I showed in the video clip - I believe I was doing the measurement correctly?
You then said you put the 6146 back into the socket, set the meter switch to IP, and keyed the transmitter which resulted in the IP meter pegged fully to the right. That is NOT a good sign!
That is correct. SG switch put to on position and tested. No change from initial fault description

If this is right, I question the 6146 tubes in your 520, one may have a short in the tube which is causing the tube to conduct fully, pegging the IP meter fully to the right.
If you have a pair of know good 6146s, remove the 6146 tubes in your 520 and put the 2 known good 6146s and repeat the test to see if the IP meter pegs.
I do have some spare tubes I can put in to test - Do I have to neutralise these for the test?? I don't want to damage the spares I have.

As Terry said, pin 5 on the 520 final amp PC board has the parasitic suppressors connected to them. A parasitic suppressor is a resistor with wire wrapped around the resistor. There is one parasitic suppressor connected to each pin 5. I should have told you that in the beginning but now you know so measure the grid voltage at the PC board connection of either one of the pin 5 grid parasitic suppressors, it doesn't matter which one the grids are wired in "parallel" and they both will have the same bias voltage.
I had no idea what a parasitic suppressor was so more knowledge gained. I can see two brown wire wrapped resistors on the board directly under the tubes. They are right near the top edge of the board . Just confirm these are what I'm supposed to measure?? I am getting no reading at all? No needle movement. Does this mean the test I did in the socket was not done correctly?
Thanks again for the responses!

The cleaning and swap didn't help. No change at all. SHOOT ME NOW!!!

This might be a dumb question but where/what is the AVR board? I don't see it on any schematic.

On an unrelated note, on the FIX board I found 2 VR's that are broken. VR2 and VR3. Those don't have anything to do with anything outside the FIX board, do they? They can't be causing these issues, can they??

The Fix Channel Board is the AVR board.

It is most commonly called the AVR board as that is the most important function that the board performs. It contains a Linear Series Pass Regulator that provides those two key voltages I previously mentioned and the -6vdc dc to dc converter. The Fixed channel function is not a critical function so people dont call the board the Fix Ch Board.

As I mentioned if cleaning relay contacts dont help then measure RF-1. Measure it at the IF board on the COM wire wrap post and on the AVR board. If VR-3 is broken then may have no RF-1 output from the AVR board. VR-2 is used to set the RIT balance so when you turn RIT on with pot centered there is no shift in frequency.

You need to start trying to read the schematic. Look at the AVR board and you will see that VR-3 taps off the 9vdc output of Q4 pass transistor and is used to drop the 9vdc to 3.3vdc to supply the AGC and ALC busses.

You can try Bob Mansker for a replacement AVR board.

I need to get back to the bench and finish customers rigs so will step away and let others help you. Have fun and be careful.

Christopher,

You don't seem to understand how voltages are written in a text document. DC (Direct Current) voltages have both positive (+) and negative (-) polarities. How the DC voltage is written depends on what polarity the DC voltage is. A "Negative DC voltage", such as negative 120VDC is written "-120VDC", note the "hyphen" to the left of the number. The same voltage written as a positive voltage is written as "+120VDC", note the "Plus" sign written to the left of the number. You need to learn this because you will see this on schematics and in written text and if you don't understand it then you will make the same mistake as you did before.

Are you using the TS-520S "Service Manual"? If not then you need to start using it. The TS-520S Final Unit PC board is shown on page 24 with the tube pin numbers shown.

Christopher,

The video clip clearly shows the bias supply, the Rectifier Unit's -C supply, is working properly so there is no need to work on the -C supply. The problem is more than likely a bad 6146, more than likely shorted internally.

Set the SG switch to ON, leave the front 6146 out of it's socket, set the meter switch to IP, and key the 520. Does the meter peg fully to the right? If it does NOT then the removed front 6146 is bad, more than likely shorted internally.

Yes, Mike, I realised this must be the case when my old analogue multi meter needle started going backwards when I reversed the probes I actually got the predicted voltages from socket pin 5 but another piece of knowledge I've picked up during this exercise.
I do have the service manual but it is largely a foreign language for me. PS1 & PS2 are the wire wound resistors which connect to Pin 5 - I couldnt get any voltage measurement from this board?
So if I have conducted the Pin 5 measurement correctly and readings are where they should be. Any suggestions as to next steps?
Trying some spare tubes was a possibility - but I gather from what I have read they should be neutralised - how is this done when you are trouble shooting a radio? Not keen to wreck spare tubes!

Christopher,

You do not need to be concerned about final amplifier neutralizing at the moment. We are only concerned about the excessive DC current flowing through the final tubes (IP meter pegs fully to the right), so RF is not part of the problem, at least it doesn't appear to be. I suspect, based on the video test results you showed, one of the 6146 final tube has an internal short. That's why I suggested using a spare set of final tubes in place of the original tubes in your 520S.

Yes, Christopher, you need a DVM which you can get on eBay or elsewhere. What ever DVM you buy, make sure it has a maximum DC voltage range of at least "1000VDC". There are some DVMs that have a lower maximum DC voltage range of approximately 750VDC. I recommend the DVM with a max of 1000VDC DC voltage.

You don't have to switch the meter leads with a DVM, it automatically tells you what the voltage polarity is by simply connecting the leads to the circuit in question.

The leads are physically sensitive and can easily break so be careful. I have gone through 2 sets of DVM meter probes, they break at the probe plug that plugs into the meter. Poor quality by the Chinese who makes most of the DVM being sold today.

I have a TS-530S that I enjoy very much. I have acquired a set of two filters (500 Hz CW, 1.8 KHz SSB) that I want to install. Although the manual seems pretty clear, i wanted to check if anybody had any "hands-on" feedback or recommendations before i open up the rig for this project. Is there anything i should be careful to watch out for or tips to doing this? Is access easy or tricky? Thanks for any advice.
Regards,
Al kj3q

Al,

Filter installation is rather straight forward. Make sure that you are using the correct filter in the correct place and move the selection wires to the correct posts. You can access the underside of the IF BOARD by removing the screws that hold it in place and GENTLY rotating it up and over to get at the "foil side." This is handy as you are not pulling out all those "molex" connectors and possible inducing a fault with a cracked or detached solder pad!

Topic: 48231 Message: 48234

Actually, filter installation is surprisingly easy and straightforward -- especially if you're using Kenwood/Trio filters.

Remove both top and bottom cabinet halves, remove the screws holding down the IF Board (which is on the top of the radio) and gently lift the board up and over to gain access to its circuit board trace side. You may have to CAREFULLY unplug a couple of connectors to make this easier and less stressful on the plugs and headers. it's best to unplug connectors with the use of needle nose or chain nose pliers so you can pull the plugs straight up rather than wiggling them side by side with your fingers (which is awkward anyway). The radio's circuit board traces are quite fragile. Caution should also be used in desoldering and soldering for the same reason.

I have installed filters in two TS-830Ss and two TS-530Ss, including a set of Inrad filters that must be wired in, with absolutely no complications.

Good luck -- and enjoy your new filters. If you're a CW guy, you'll love them.

Joe is right on both counts. You don't really need to unplug anything if you're gentle with the board and, as he said, don't forget about setting the jumpers correctly (the procedure's in the manual and very easy to do).

No Bob, I actually meant max 1KV rated DC voltage switch setting.

The DMM's 1000VDC switch setting or a DMM with auto voltage ranging, is not the "minimum" voltage the meter can measure but rather the maximum DC voltage the DMM can measure.

For example, I have the Excel DT9205A and the Rolls MU188 DMMs. Both have a DC voltage switch setting of 1000V. That DC voltage setting is the "maximum" DC voltage level the DMM can measure. The same applies to the "AC" switch setting or auto ranging the DMM has, the maximum voltage the meter can measure.

Bill,

It's possible.

Christopher, make a video or take a picture showing the bottom of the final amplifier so we can see the resistors. There are two 10 ohm 1 watt cathode resistors that if they are open then the meter will peg fully to the right even with a good pair of 6146s.

Another clip to review. I have conducted the tests Mike suggested.
Removal of one tube with SG switch turned on
Meter in ALC position - little movement & no response when drive is adjusted
Meter in IP position - no movement of needle in tune, CW or SSB
Meter in RF position - as above
I did the same test with the front tube removed with the same result.
I put in two spare tubes. With SG switched on - meter pegs in IP mode as previously.
You will also see in the clip after entering tune, the receive side of the radio is substantially reduced. A power on/off restores recv.?
I don't know if this is related but best resolve TX issue to start with.

I've made this clip of the PA board to show the resistors.
https://www.youtube.com/watch?v=4_KbBC_iOYE&feature=youtu.be
https://www.youtube.com/watch?v=4_KbBC_iOYE&feature=youtu.be
From looking in the manual I take it the cathode resistors are R2 & R3 - provided I'm reading the diagram correctly - AKA the pink ones. Brown, Black Black bands = 10 ohms - There has definitely been some work done to this board previously - but given the radios age - hardly surprising.

Both the pink resister appear to measure open - needle doesn't budge on the MM and measuring the same resistors on the other 520 yields resistance of 7 or 8 ohms. Replacement of these two resistors look to be the next step.- Comments?

Hi ALL , Do any members know the solution to the AGC voltage gate 2 voltage on Q4 &Q8 being low when switching the set on from cold . The voltage should be 2.9 volts , but can be as low as 1.3 volts . this rail voltage is measured wiyh the agc off . After about 1 hour the voltage will rise to the correct voltage . I have replaced Q4 , Q8 Q2 Q3 C60 . the s meter driver transistor has also been replaced along with the agc timing capacitors but the fault still persists . Any loading of the agc rail seems to affect the 2.9 volt rail . i would be interested to know of any other people having this fault .

Christopher,

Okay, there's been a misunderstanding as to what you meant when you said the "IP meter pegging". I watched your video and I was waiting for the IP meter to peg fully to the "right" but the meter simply dropped to "zero" so that changes what I thought was happening.

You said you were going to check the resistors on the final PC board. Although the cathode resistors appear to be okay I would suggest you measure the cathode resistors to ensure they are okay.

When measuring the resistance of any resistor, make sure power is turned OFF and the HV filter capacitors are bled to zero. Use your volt meter to ensure the caps are bled down to zero.

By the way, the HV appears to be fine, +900VDC with the transmitter keyed. We need to find out why there is no IP idling current in the final amplifier.

To measure the resistors, connect your ohm meter lead across one of the larger resistor, color band should be BROWN BLACK BLACK and see approximately 5 ohms.

Remember, although both cathode resistors are 10 ohms, when they are soldered in the circuit the resistor are in "parallel" resulting in the resistance only being half, i.e., only 5 ohms.

The formula to determine the resistance value for 2 resistors in parallel is:

10 x 10 / 10 + 10 = 5 ohms

I used the 10 ohm cathode resistor values in the example.

You should also measure the final tube screen resistors, they are the smaller darker color banded resistors, BROWN BLACK BROWN. Connect the ohm meter across each screen resistor and you should see approximately 100 ohms.

Next, measure the meter multiplier resistors, it's the 3.3K with color bands ORANGE ORANGE RED. The meter multiplier resistor should be close to 3300 ohms (3.3K).

Ken,
I found that the switch, when pressed, also grounds it to the metal strip that acts as a backing, preventing proper switching. So I can fix that so it doesn't do that.
With that fixed, when switching it on now, the rig does go to zero on the meter. I also noted that when releasing it, the meter jumps up very high, depending on how high the carrier is set for. Not sure if that's normal.
I tired again with the mic attached and it still doesn't register my voice. I checked again the element with the V-meter and it is still responding.
So either the rig isn't responding to my voice and it really is working, or there is something else going on with the mic. I think I'll try making a contact to see if I get any response.

Alan:

No offense man but you are "easter egging". Very seldom do any of the active devices (dual gate mosfets) that you are changing ever fail. All this constant pulling of the IF board can result in damage and cause latent fault to bite you later (cracked molex pin pad to trace).

Yes the AGC rail by design is a very high impedance power supply (fed thru 2.2meg resistor) and has to be inorder for Q10 AGC amp to cause the dc control voltage to Gate 2 of these gain controlled devices to drop from it 3.6vdc and reduce the gain in presence of strong off air signals. Virtually any load including a 11 meg VTVM applied to the AGC bus will pull the voltage down and drive the S-meter up scale.

What is RF-1 doing at the Audio Board during all this. It should stay at nice steady 3.6vdc. If RF-1 is varying then the AGC rail will follow. If RF-1 is varying what is the 9vdc regulated doing? If it is stable try cleaning VR-3 trim pot on Audio board.

What is the S-meter doing in Slow with RF gain full CW? At 2.9vdc it should be reading up scale.

With rig down powered and AGC bus discharged what is the resistance that you read from the AGC bus to chassis ground?

Larry,

OK on the switch repair. It sounds like you have the PTT wiring straightened out. Did you run through all of my suggested continuity tests to verify that the mic element isn't getting grounded anywhere after this last fix and after you reassembled the entire mic head and stand?

Also, with the mic fully assembled but not connected to the rig, did you try connecting your meter to pins 1 and 4 of the plug to see if you get the same reaction you did when putting the meter directly across the mic element? Since the wires from pins 1 and 4 are supposed to go directly to the terminals on the back of the mic element the meter should read the same. If it does not then there is still a wring problem.

I'm confused about your statement "I also noted that when releasing it, the meter jumps up very high, depending on how high the carrier is set for.". When you release the PTT bar the rig switches from transmit to receive and begins displaying the received signal strength. In receive the meter acts only as a received signal strength, or "S", meter. It can not display ALC, Ip, RF output, HV (High Voltage), or carrier(?) regardless of the meter switch position. It may be you are misusing the term "carrier" in this context. Can you describe what control you used to set this carrier level that is being displayed when the PTT is released?

Don't give up! You are very close...

Alan

I forgot to give you the typical AGC rail resistance measurements.

1. At Conn 15 pin 3 on IF board = 2.2 meg ohm
2. Carefully pull Conn 8 on IF board and measure again at Conn 15 = 4.7 meg ohm

In the old days we use to get excited if the "AVC" bus was less than approx 10 meg ohm, but the KW hybrid works fine around 4.7 meg ohm. Was in a great while you will find a leaky AGC timing cap but not very often.

Best meter I know of for AGC and ALC bus work is the old HP-410B and C that have over 100meg input Z and the rails wont know the meter is hanging on them.

I have never seen a leaky Q11 S-meter FET. If it is bad it usually shorts and pulls the AGC bus down and pegs the S-meter and shuts down the receiver.

Again I would want to make sure that reference voltage RF-1 is stable and not slowly moving up or down. Not common for it to do that.

Hello Terry thanks for your reply , I will look at all the things you have mentioned over the next couple of days .
The problem i have had and the reason i am struggling with this TS- 830 , IS THAT A FELLOW HAM removed the CW filter and on replacing the IF BOARD he reversed plugs 8&9 on the I.F board .These connections are next to each other and both 5 pin . I have checked RF 1 and i think it was just under 3.6 volts but stable .
Reversing PLUGS 8&9 on the I.F board took out the I.F & mixer mossfets . I find human error faults are the worst to find . I will contact you again after more inbvestigations . 73

From: <crgrbrts@...>
Topic: 48250 Message: 48250

My TS-830S still suffers from two transmit anomalies; possibly or probably related:

On 40 meters, peaking of the RF drive coil must be accomplished at the low end of the band (like 7.010 MHz), rather than at the instructed 7.150 MHz. Otherwise, drive at that end of the band -- as indicated by ALC metering in TUNE -- is "glitchy" with double peaks and erratic response.

On 10 meters at 28.800 MHz, peaking of the RF Drive coil must be accomplished with the Drive control set at about 2 o'clock rather than the instructed 12 o'clock. Otherwise there is no Drive as indicated by ALC metering and power output is low. All is normal if the drive coil is peaked with the drive control at 2 o'clock.

It has been suggested by a Drake tech -- who also works on Kenwoods from time to time -- that band pass filter misalignment (via the PLL board) is the culprit. Can this be so and, if so, can BPF alignment be accomplished without the requisite sweep generator, etc.?

Thanks and 73,

Craig

Brian,

 The IF BOARD (48-1310-00) has provision for 3 installed filters.

Usually you will see just the YK-88S...this is filter for SSB

 Then you have another space for a YK-88C or YK-88CN...these are CW filters

  Then you have another space for a YK-88SN...another SSB filter

  The "N" stand for narrow.

  The jumpers in question are right next to connector #5.

  Look at Pg. 23 of the TS-530S Instruction Manual.

Yes, you can install both the 500 Hz (or 250 Hz) and 1.8 KHz SSB filters in the TS-530S. I did so on mine. With the jumpers connected correctly, the "normal" CW bandwidth will now be 1.8 KHz with "Narrow" selection at 500 Hz (or 250 Hz). In SSB, normal bandwidth will be the stock 2.4 KHz with 1.8 KHz being the "Narrow" selection.

It's slick.

OK I made an assumption based on what I see and read on various forums. Lot of changing out of active devices instead of troubleshooting. Yes sure doesnt help when human error is the root cause. I still take photos and make drawings after 10 years and can almost see these boards in my sleep!

OK if RF-1 is little low no problem easy to adjust and a little low is not your problem. Might clean the RF gain pot if you have not already done so and also meter the RFG pin at Conn 8 on the IF board and see if it is stable at power on and warm up. RFG should not move as it is fed by RF-1 thru the RF gain pot.

Craig:

Sounds like been talking to SAJ.

You may want to wait and see what other TS830 owners have to say but here is my two cents.

Have you done Step 9 of the Service Manual yet? If not do it before you worry about looking at the BPFs. Need a DMM applied to TP-1 to measure and adjust the Varactor diode control voltage and a Freq counter at D40 to measure VCO frequency and means to measure the VCO voltage level at the RF board at each end of the VFO range. Should not be any less than 800mv. Typically will be 1.0 to 1.5 rms rf volts at VFO 250 position. Can measure with RF probe/ VTVM, RF millivolt meter, or O-scope.

Yes couple of ways to check the BPF response without a Sweep Gen. Can verify the center frequency (Fc) just by using the VFO and a RF millivolt meter or O-scope at Emitter of Q35. I use a micro-grabber test lead to clip on the emitter lead. Cant look at Fl or Fh as the VFO range will not go low or high enough. But if Fc is very close not likely anyone has messed with the BPF coils.

Also can check the frequency response the old fashioned way and unplug the VFO input to the PLL and use standard RF sig gen to inject 50 to 100 khz steps and record the RF output voltage and then plot the levels on graph paper. A little tedious but can get a nice accurate look at what the response curves looks like now. Just not a practical method for making any needed adjustments.

If you have problems meeting the acceptance criteria of Step 9 then come back and we can talk more specifics of how to obtain a response curve for all three filters without a sweep generator. Of course you could buy a spectrum analyzer and tracking generator or a 2 port VNA and when finished keep them at my house!

I may have spoken too soon. The TS 530 has a major problem. Yesterday, I had several cw contacts. Today, I cut the radio on and the smeter pegs with no receive. There is a slight hiss that can be increased-decreased by the volume control. The vfo, display is fine. I have the sg switch and heater off. The front controls are set correctly. Something happened internally since operating yesterday.

The s meter stays pegged unless I switch to tune and send.

Has anyone see this before?
